CHAPTER I.

PLAN AND SCOPE OF INQUIRY.

I. Provisions of law 1–3
II. Development of mining statistics 3–18
Table 1.—Character of inquiries concerning mines and quarries: 1850 to 1902 4
Table 2.—Subjects included in Census reports concerning mines and quarries: 1850 to 1902 ..... 4, 5
Table 3.—Mining statistics reported at censuses: 1850 to 1902 6
Census of 1870 6
Census of 1880 ..... 6, 7
Census of 1890 7–9
Table 4.—Summary of mineral industries: 1889 8
Census of 1902 9
Mining and manufacturing 9–14
Special schedules 14, 15
Expert special agents 15, 16
Collaboration with the United States Geological Survey 16–18
III. Difficulties and defects of the enumeration 18–22
IV. Office and field work 22–24
V. Classification of minerals 24–35
Percentage of metal contained in ores of economic importance 33–35

CHAPTER II.

SUMMARY AND ANALYSIS OF RESULTS.

I. General review of the mining industry 36–55
Table 1.—Summary: 1902 36
Table 2.—Comparative statement, quantities and values of minerals: 1902 and 1889 ..... 36, 37
Decreases in 1902 ..... 38, 39
Early development 39, 40
Rank of the United States in mining 41, 42
Table 3.—Production of coal, iron ore, copper, lead, gold, and silver in the principal producing countries: 1902 41
Increase since 1880 42–44
Table 4.—Increase in population and in value of agricultural products, manufactures, and mineral products: 1880 to 1900 42
Table 5.—Mineral products: 1892 to 1902 42
Leading minerals 44
Table 6.—Summary for leading minerals, and percentage each formed of total: 1902 44
Table 7.—Summary for metallic and nonmetallic products: 1902 44
Table 8.—Summary for minerals grouped according to character of ores and uses: 1902 45
Table 9.—Percentage each group of minerals forms of total: 1902 48
Mineral products by states 48–51
Table 10.—Summary by states and territories: 1902 50
Table 11.—Rank of states and territories in population, agriculture, manufactures, and mining 50, 51
Mineral products by geographic divisions 54, 55
Table 12.—Population, value of agricultural products, manufactures (gross and net), and mineral products, with rank of each, by geographic divisions 55
II. Development work 55–57
Table 13.—Productive and unproductive mines, quarries, and wells: 1902 56
Table 14.—Development work, by states and territories: 1902 57
III. Limitations of the use of census statistics of mining 57, 58
IV. Number of mines, quarries, and wells 58–60
Number of producing mines for principal minerals: 1902 and 1889 59
Table 15.—Number of active and idle mines by classification of minerals: 1902 60

	Page.
V. Number of operators	60–64
Table 16.—Average number of wage-earners, wages, and value of products per operator, for the principal minerals: 1902	60
Large and small operators	61
Table 17.—Number of operators and value of their products, grouped by minerals into classes based on value of product: 1902	61, 62
Table 18.—Number of operators, classed by value of product, with percentage each class is of total: 1902	62, 63
Table 19.—Number of operators, natural gas and petroleum, classed by value of product: 1902	64
Table 20.—Natural gas and petroleum, classed by value of product, with percentage each class is of total: 1902	64
VI. Character of ownership	64–74
Table 21.—Number of operators and value of product, by character of ownership: 1902	65
Table 22.—Per cent distribution, by character of ownership, of number of operators, and value of product for each mineral and group of minerals: 1902	66
Individual ownership	66, 67
Firms or partnerships	67
Incorporated companies	67
Table 23.—Comparison of statistics for incorporated companies and for all other forms of ownership, by minerals, and groups of minerals: 1902	68–70
Petroleum	72
Table 24.—Summary for petroleum for incorporated and unincorporated operators: 1902	72
Industrial combinations	72–74
Table 25.—Summary for minerals for which industrial combinations are reported: 1902	74
VII. Capital	74–89
Reasons for not securing statistics	74, 75
Capitalization of incorporated companies, by minerals	75–80
Table 26.—Capitalization of incorporated companies, by minerals and groups of minerals: 1902	78, 79
Dividend paying companies	80–84
Table 27.—Capitalization of incorporated companies paying either dividends on stock or interest on bonds, by minerals: 1902	82, 83
Table 28.—Capital stock of incorporated companies paying dividends on common or preferred stock, by minerals: 1902	84
Common stock	84, 85
Table 29.—Common stock of incorporated companies paying dividends on such stock: 1902	85
Table 30.—Capitalization of incorporated companies paying dividends on preferred stock but not on common stock: 1902	85
Preferred stock	86
Table 31.—Preferred stock of incorporated companies paying dividends on such stock, by minerals: 1902	86
Bonds	86
Table 32.—Bonds of incorporated companies paying interest on bonds, by minerals: 1902	86
Natural gas and petroleum	86, 87
Table 33.—Capitalization of incorporated companies producing natural gas and petroleum and reporting capitalization: 1902	87
Table 34.—Capitalization of natural gas and petroleum companies paying dividends or interest on bonds: 1902	87
Capitalization of incorporated companies, by states and territories	87–89
Table 35.—Capitalization of incorporated companies, by states and territories: 1902	88, 89
VIII. Employees and wages	90–101
Table 36.—Employees by classes: 1902	91
Table 37.—Distribution of wage-earners according to occupations, by minerals and groups of minerals: 1902	92
Table 38.—Wage-earners, men and boys, by minerals: 1902	93
Table 39.—Average number of wage-earners employed during each month: 1902	94
Table 40.—Average number of wage-earners employed during each month, by minerals, in the mining of which more than 2,000 were employed: 1902	95
Average earnings of wage-earners	95, 96
Wage-earners at specified daily rates of pay	96–101
Table 41.—Distribution of wage-earners according to daily rates of pay, by minerals: 1902	96, 97
Table 42.—Average number of wage-earners, and per cent of total number, at specified daily rates of pay, by occupations: 1902	99
Table 43.—Average number of wage-earners at specified daily rates of pay, by states and territories: 1902	100
Table 44.—Distribution of wage-earners according to daily rates of pay, by geographic divisions: 1902	101
IX. Contract mining and quarrying	101–104
Table 45.—Comparison of contract miners with all miners, by minerals: 1902	102
Table 46.—Wages paid for contract coal mining, and amount paid in allowances, by states and territories: 1902	103
X. Contract work	104–106
Table 47.—Comparison of contract work with value of product, by minerals: 1902	104
Table 48.—Contract work at nonproducing mines, by minerals: 1902	106
XI. Production without employees	106, 107
Table 49.—Production without employees, by minerals: 1902	107

Page.
XII. Irregular producers 107, 108
XIII. Time in operation 108–111
Table 50.—Time in operation: 1902 ..... 109, 110
XIV. Miscellaneous expenses 111–114
Table 51.—Miscellaneous expenses, by groups of minerals and percentage each group is of total: 1902 111
Royalties and rent 111–114
Table 52.—Coal, anthracite—number of operators at various rates of royalty: 1902 111
Table 53.—Coal, bituminous—number of operators in each state at various rates of royalty: 1902 112
XV. Cost of supplies and materials 114, 115
Table 54.—Cost of supplies and materials, and percentage this is of value of product, by minerals and groups of minerals: 1902 115
XVI. Power and machinery 115–122
Table 55.—Number of operators reporting use of power and the value of their products compared with totals for all operators, by minerals and groups of minerals: 1902 116
Table 56.—Horsepower: 1870 to 1902 117
Table 57.—Number of operators reporting the use of the different kinds of power, and total horsepower: 1902 118
Per cent of each kind of power employed in the different groups of minerals: 1902 119
Per cent of operators reporting power, and per cent of these reporting steam, gas, water, or other power, by groups of minerals: 1902 119
Number of hoisting and pumping engines employed in gold and silver and copper mining: 1902 120
Power driven mining and ore dressing machinery 120–122
XVII. Quantity and value of products 122–126
Scope of the statistics 122, 123
Standard of measurement 123
Table 58.—Production and commercial value of silver 123
Table 59.—Production of anthracite and bituminous coal 123
Value of products for 1902 124–126
Value of products for groups of minerals and percentage each is of the total: 1902 124
Value of products by geographic divisions: 1902 124
Value per unit of measure 125, 126
Table 60.—Comparative summary of quantity, value, and average value per unit of measure of products for selected minerals: 1902 and 1889 125
By-products 126
Abrasive materials and the quantity and value of such materials obtained from quarries included under other classifications: 1902 126
XVIII. Mining operations of governmental institutions 126–129
Table 61.—Summary, mining operations of governmental institutions: 1902 127
Table 62.—Mines, quarries, and natural gas wells operated by the United States and city or town governments: 1902 127
Penal institutions 128
Table 63.—Mines and quarries operated by penal institutions: 1902 128
Eleemosynary institutions 128, 129
Table 64.—Quarries and natural gas wells operated by eleemosynary institutions: 1902 129
XIX. The verification of the mining census 129–131
Comparison with Geological Survey 129–131
Table 65.—Comparison of minerals and mineral products reported by the Bureau of the Census and the Geological Survey: 1902 129
Comparison with state reports 131
Table 66.—Yearly production of coal as reported by United States Census and state offices 131
XX. Mining and manufacturing 131–135
Table 67.—Mining and manufactures: 1902 and 1900 132
Table 68.—Interdependent growth in the mining and manufactures of coal and iron in Alabama and Colorado: 1902 and 1889 133
Table 69.—Value of mine and quarry products and manufactures thereof, by geographic divisions 134
Table 70.—Movement of iron ore on the Great Lakes: 1902 134
Table 71.—Mine and quarry products and the chief manufacturing industries utilizing same 135
XXI. Exports and imports of minerals 136–143
Table 72.—Exports of domestic merchandise and products of mines, exclusive of gold and silver and phosphate rock: 1889 to 1902 136
Table 73.—Value of exports of products of mines, including crude mineral oils: 1889 to 1902 136
Table 74.—Value of production and imports of certain comparable minerals: 1902 137
Table 75.—Imports for consumption: 1889 to 1902 140–143

CHAPTER III.

ELECTRICITY IN MINING. By Thomas Commerford Martin 145–161
Table 1.—Electric power, by minerals: 1902 146
Power generation and transmission 146–149
Coal cutting machinery 149–151
Drills 151
Shot firing 151, 152

ELECTRICITY IN MINING—Continued. Page.
Mining traction ... 152–155
Telpherage ... 155
Hoisting ... 155, 156
Pumping ... 156, 157
Lighting ... 157–159
Ventilation ... 159
Placer mining ... 159, 160
Miscellaneous uses of electricity ... 160, 161

MINES AND QUARRIES BY STATES AND TERRITORIES.

Introductory statement ... 165
Alabama ... 166–169
Arizona ... 170–172
Arkansas ... 173–176
California ... 177–182
Colorado ... 183–188
Connecticut ... 189–191
Delaware ... 192, 193
Florida ... 194–196
Georgia ... 197–202
Idaho ... 203–205
Illinois ... 206–209
Indian Territory ... 210, 211
Indiana ... 212–214
Iowa ... 215, 216
Kansas ... 217–220
Kentucky ... 221–224
Louisiana ... 225
Maine ... 226–228
Maryland ... 229–233
Massachusetts ... 234–236
Michigan ... 237–240

GENERAL TABLES.

Table 1.—Detailed summary, by minerals and groups of minerals: 1902 ... 348–361
Table 2.—Detailed summary, by states and territories: 1902 ... 364–377
Table 3.—Detailed summary, states and territories, by minerals: 1902 ... 380–391

REPORTS ON SEPARATE MINERALS.

Page.

IRON ORE. By John Birkinbine 393–431
Table 1.—Comparative summary: 1880 to 1902 395
Development work 396, 397
Table 2.—Development work, by states: 1902 397
Capital stock of incorporated companies 397–399
Table 3.—Capitalization of incorporated companies: 1902 398
Employees and wages 399–402
Table 4.—Average number of wage-earners employed during each month, by states and territories: 1902 399
Table 5.—Tons of iron ore produced per wage-earner, by states: 1902 and 1889 399
Table 6.—Distribution of wage-earners according to daily rates of pay, by states and territories: 1902 400
Table 7.—Distribution of wage-earners according to daily rates of pay: 1902 401
Mechanical power 402
Production 402–406
Production of iron ore: 1860 to 1902 402
Table 8.—Production of iron ores by varieties, with per cent of total: 1902, 1889, and 1880 403
Table 9.—Production of iron ore, by states and territories and varieties 403
Minnesota 403, 404
Production and value of Minnesota iron ore: 1889 and 1902 404
Michigan 404
Production and value of Michigan iron ore: 1880 to 1902 404
Alabama 404
Production and value of Alabama iron ore: 1880 to 1902 404
Virginia and West Virginia 404
Production and value of Virginia and West Virginia iron ore: 1880 to 1902 404
Tennessee 404
Production and value of Tennessee iron ore: 1880 to 1902 404
Pennsylvania 404, 405
Production and value of Pennsylvania iron ore: 1880 to 1902 405
Wisconsin 405
Production and value of Wisconsin iron ore: 1880 to 1902 405
New York 405
Production and value of New York iron ore: 1880 to 1902 405
Other states and territories 405
Table 10.—Quantity and value of iron ore, by states and territories: 1880 to 1902 405
Table 11.—Summary, by districts: 1902 405
Imports 406
Table 12.—Quantity and value of iron ore imported: 1889 to 1902 406
Descriptive 406–425
Production of pig iron: 1894 to 1902 406
Classification of iron ore 407, 408
Distribution of ore deposits 408–415
The Lake Superior region 409–411
Production of Lake Superior iron ore, 1893 to 1902, with previous shipments 409
Typical analyses of Lake Superior iron ores 411
Analyses of siliceous ores 411
Alabama-Tennessee, or Southern district 411
Production of iron ores, Southern district, by states and varieties: 1902 411
New York and New England 411–413
New Jersey 413
Pennsylvania 413, 414
Delaware and Maryland 414
The Virginias and Carolinas 414
Ohio 414
Wisconsin and Iowa 414
Missouri and Arkansas 414
Texas 414
Rocky Mountain region 414, 415
Value of iron ore deposits 415, 416
Commercial value of the product 416, 417
Table 13.—Quantity, value, and average value per ton of iron ore, by states and territories: 1899 to 1902 417
Mining methods 417, 418
Fine ores 418–420
Concentration of iron ores 420
Roasting iron ores 420–422
Advantages of mixing iron ores 422

IRON ORE—Continued.
Descriptive—Continued. Page.
Classification of iron ore production ... 422, 423
Production of iron ore in large mines ... 423
Contemporaneous production of iron ore in the United States, Great Britain, and Germany ... 423
Table 14.—Detailed summary: 1902 ... 426–431
MANGANESE ORE. By John Birkinbine ... 433–442
Table 1.—Comparative summary: 1880 to 1902 ... 435
Capital stock of incorporated companies ... 435
Table 2.—Capitalization of incorporated companies: 1902 ... 435
Employees and wages ... 435, 436
Production ... 436
Table 3.—Production of manganese ores: 1893 to 1902 ... 436
Table 4.—Production and value, and average value per ton, of manganese ores, by states: 1902 ... 436
Table 5.—Production of manganese ores, by states: 1889 to 1902 ... 436
Imports of manganese ore ... 437
Table 6.—Imports of manganese ore, by countries: 1902 ... 437
Table 7.—Imports of manganese ore: 1889 to 1902 ... 437
World's production ... 437, 438
Table 8.—World's production of manganese ores ... 437
Value of manganese ores ... 438
Prices paid for manganese ore delivered in the Pittsburg (Pa.) district ... 438
Manganiferous iron ores ... 438, 439
Production of manganiferous iron ores: 1902 ... 438
Table 9.—Production of manganiferous iron ores: 1889 to 1902 ... 439
Argentiferous manganiferous iron ores ... 439
Manganiferous zinc ores ... 439
Useful minerals produced containing manganese in notable proportions: 1902 and 1889 ... 439
Review of the industry by states ... 439, 440
Arkansas ... 439, 440
California ... 440
Colorado ... 440
Production of manganiferous ores in Colorado: 1902 and 1889 ... 440
Georgia ... 440
Montana ... 440
South Carolina ... 440
Virginia ... 440

Table 8.—Summary for dividend paying and nondividend paying companies: 1902 ... 448
Employees and wages ... 448–450
Table 9.—Average number of wage-earners employed during each month, by states and territories: 1902 ... 449
Table 10.—Distribution of wage-earners according to daily rates of pay, by occupations: 1902 ... 449
Table 11.—Lead and zinc mines, classified by number of days in operation, by states and territories: 1902 ... 450
Mechanical power ... 451
Table 12.—Steam engines, by states and territories: 1902, 1880, and 1870 ... 451
Production ... 451–453
Value of the lead and zinc product: 1902 ... 451
Table 13.—Quantity, total value, and average value per ton of lead and zinc ore, by states and territories: 1902 ... 451
Table 14.—Comparative summary, quantity and value of lead ore, by states and territories: 1902 and 1889 ... 452
Table 15.—Comparative summary, quantity and value of zinc ore, by states and territories: 1902 and 1889 ... 452
Quantity and value of lead and zinc ore, Census and Missouri mine inspector's returns: 1902 ... 452
Table 16.—Comparative summary, lead and zinc mines, Missouri: 1902, 1880, and 1870 ... 453
Table 17.—Comparative summary of mines producing lead ore only, Missouri: 1902 and 1889 ... 453
Table 18.—Quantity and value of zinc ore, Missouri: 1873 to 1902 ... 453
Lead contents of lead and zinc ores ... 453, 454
Zinc contents of lead and zinc ores ... 454
Table 19.—Zinc contents of ores mined in the principal producing states: 1902 ... 454

LEAD AND ZINC ORE—Continued. Page.
General summary of lead and zinc mines, by states and character of mine ... 454, 455
Table 20.—Summary of lead and zinc mines, by states: 1902 ... 454
Table 21.—Summary of mines, by character of product: 1902 ... 455
Table 22.—Summary for mines producing zinc ore exclusively, by districts: 1902 ... 455
Table 23.—Summary for mines producing lead ore exclusively, by districts: 1902 ... 455
Auriferous and argentiferous lead and zinc ores ... 455, 456
Value of lead and zinc in all ores, by sources of production: 1902 ... 455
Assay contents of the zinc ores of Colorado: 1902 ... 456
Classification of zinc bearing ores of Colorado by the commercial value of the principal metals: 1902 ... 456
Consumption of zinc ore ... 456, 457
Production and consumption of zinc: 1902 ... 457
Tendency toward centralization ... 457–459
Table 24.—Classification of lead mines by value of product: 1902 ... 457
Table 25.—Classification of zinc mines by value of product: 1902 ... 457
Missouri ... 457
Table 26.—Classification of lead mines, Missouri, by value of product: 1902 ... 457
Table 27.—Classification of zinc mines, Missouri, by value of product: 1902 ... 458
Table 28.—Lead mines of Missouri, acreage owned, and value of product: 1902 ... 458
Table 29.—Zinc mines of Missouri, acreage owned, and value of product: 1902 ... 458
Table 30.—Depth of shaft and value of product in Missouri: 1902 ... 459
Production on a small scale ... 459
Table 31.—Average production for all mines and for those using hand and animal power only, by states: 1902 ... 459
Table 32.—Number and value of production of mines without mechanical power, by states: 1902 ... 459
Table 33.—Summary for mines operated without mechanical power, by states: 1902 ... 459
Descriptive ... 459–463
Methods of mining and smelting ... 460, 461
Utilization of zinc ore ... 461
Business organization ... 461, 462
Mining in a small way ... 462, 463
Table 34.—Detailed summary: 1902 ... 463–465
COPPER ORE. By Isaac A. Hourwich, Ph. D ... 467–506
Table 1.—Comparative summary: 1860 to 1902 ... 469
Development work: 1902 ... 469
Number of mines and operators ... 470
Character of ownership ... 470
Table 2.—Summary, by character of ownership: 1902 ... 470
Capital stock of incorporated companies ... 470–473
Table 3.—Capitalization of incorporated companies: 1902 ... 471
Table 4.—Incorporated companies grouped by class of stock: 1902 ... 472
Table 5.—Capitalization of the Amalgamated Copper Company and its constituent companies: 1902 ... 472
Dividends ... 472, 473
Table 6.—Incorporated companies, classified with relation to dividends, capital stock, and bonds: 1902 ... 472
Classes of stock and bonds on which dividends and interest were paid: 1902 ... 473
Table 7.—Comparative summary of dividend paying and nondividend paying companies: 1902 ... 473
Employees and wages ... 473–475
Table 8.—Average number of wage-earners employed during each month: 1902 ... 474
Table 9.—Distribution of wage-earners according to daily rates of pay, by occupations: 1902 ... 474
Table 10.—Distribution of wage-earners according to daily rates of pay, by states: 1902 ... 475
Days in operation ... 475
Table 11.—Number of mines, classified according to time in operation, by states and territories: 1902 ... 475
Miscellaneous expenses ... 475, 476
Supplies and materials ... 476
Mechanical power ... 476–478
Horsepower used and tons mined, by states and territories: 1902 ... 476
Steampower used: 1902, 1880, and 1870 ... 477
Table 12.—Hoists, pumps, and power drills, in Western and Southern states and territories, classified by kind of power used: 1902 ... 477
Tonnage mined and wages paid to miners and miners' helpers in mines with and without power drills: 1902 ... 477
Production ... 478–481
Table 13.—Copper contents of all ores mined, and production of copper mines, values less charges: 1902 ... 478
Table 14.—Bullion contents of copper ores sold and treated, by states and territories: 1902 ... 479
Average price per pound of copper in the ore, by states and territories: 1902 ... 479
Method of treatment of copper ore: 1902 ... 479
Copper contents and gross value of western crude ores: 1902 ... 479
Table 15.—Value of ore sold and smelted by owner, cost of reduction, and value at mine, by states and territories: 1902 ... 480
Cost of reduction of ores: 1902 ... 481

COPPER ORE—Continued. Page.
Mines and mills ... 481, 482
Table 16.—Summary of mines combined with mills where separately reported: 1902 ... 482
Table 17.—Summary, exclusive of mills, for mines with mill connections compared with mines not connected with mills: 1902 ... 482
Comparison by geographic divisions ... 482, 483
Table 18.—Production of the United States, and of the Lake Superior, Montana, and Arizona districts: 1883 to 1902 ... 482
Table 19.—Comparative summary of western, Lake Superior, and southern copper mines: 1902 ... 483
Lake Superior district ... 483, 484
Table 20.—Comparative summary, Michigan: 1860 to 1902 ... 483
Steam engines and horsepower in Michigan: 1902, 1880, and 1870 ... 483
Production and dividends of Lake copper mines, by quadrennial periods: 1879 to 1902 ... 484
Capital stock issued and total dividends paid since organization by Lake Superior mining companies ... 484
Quincy Mining Company: 1866 to 1902 ... 484
Montana, Arizona, and New Mexico ... 484, 485
Table 21.—Comparative summary for Arizona, Montana, and New Mexico: 1902 and 1889 ... 485
Smelters connected with mines ... 485
Table 22.—Summary of smelters and refineries connected with mines: 1902 ... 485
Copper contents of all ores mined, including gold and silver ores ... 485, 486
Copper contents of all ores mined, by sources of production: 1902 ... 485
Table 23.—Copper contents of all ores mined, by states and territories: 1902 ... 486
Consumption of copper ores ... 486, 487
Production of metallic copper and matte in the United States: 1902 ... 486
Mineral lands ... 487, 488
Table 24.—Summary of mineral lands, by states and territories: 1902 ... 487
Table 25.—Number of mines operating exclusively on leased lands, acres leased, value of product, and royalties paid: 1902 ... 487
Table 26.—Acreage of mineral lands, by states and territories: 1902 ... 488
Table 27.—Acreage owned and leased, and value of product: 1902 ... 488
Concentration of the industry ... 488–490
Table 28.—Acreage of mineral lands, by districts: 1902 ... 488
Table 29.—Classification of copper mines by value of production: 1902 ... 488
Production of the United Copper Company: 1902 and 1901 ... 489
Percentage production of eleven companies formed of total: 1902 ... 489
American production of copper, as reported by the American Producers' Association: 1892 to 1902 ... 490
Number of shareholders in Lake copper companies: 1896 to 1902 ... 490
Production on a small scale ... 490–491
Table 30.—Summary of mines using only water wheels, or gas or gasoline engines: 1902 ... 490
The world's production and the world's copper market ... 491–498
Table 31.—Production of copper mines of the world: 1879 to 1902 ... 491
Table 32.—Copper output of mines and smelters of all countries: 1889 to 1902 ... 492
Table 33.—Growth of the world's copper production in the nineteenth century ... 492
Table 34.—Output of copper mines of the United States and other countries, by quadrennial periods: 1879 to 1902 ... 492
Table 35.—World's production and consumption of copper, by countries: 1895 to 1902 ... 493, 494
Table 36.—World's production, domestic consumption, and supply available for export, with per cent of total production: 1895 to 1902 ... 494
Table 37.—Consumption of copper in importing countries and exports of domestic copper from the United States: 1895 to 1902 ... 494
Table 38.—Trade of the principal exporting countries with Europe: 1895 to 1902 ... 495
Table 39.—Copper consumption of Great Britain, Germany, and France, and imports from the United States: 1895 to 1902 ... 496
International organization among producers ... 496–498
Table 40.—World's production and output of American and foreign reporting mines: 1893 to 1902 ... 498
Prices ... 498–504
Table 41.—Average prices of copper, London and New York: 1879 to 1902 ... 498
Supply and demand and prices in the United States: 1900 to 1902 ... 500
Production, prices, and dividends: 1895 to 1902 ... 504
Table 42.—Detailed summary: 1902 ... 504–506
GOLD AND SILVER. By Isaac A. Hourwich, Ph. D ... 507–589
Table 1.—Comparative summary: 1860 to 1902 ... 510
Development work ... 510
Table 2.—Comparative summary of productive and of developing and producing mines without mill connection in the United States: 1902 ... 510
Number of mines and operators ... 510, 511
Table 3.—Mining prospects upon which assessment work was done, by states and territories: 1902 ... 511
Table 4.—Distribution of mining prospectors by number of claims held: 1902 ... 511
Character of ownership ... 511–513
Table 5.—All mines, classified by character of ownership: 1902 ... 512
Table 6.—Producing mines, classified by character of ownership and value of product: 1902 ... 512
Table 7.—Summary for all mines, by character of ownership: 1902 ... 512

GOLD AND SILVER—Continued. Page.
Location of general offices of mines by cities: 1902 ... 513
General offices, whether within or without the state where the mine is situated: 1902 ... 513
Capital stock of incorporated companies ... 513–518
Table 8.—Capitalization of incorporated companies operating producing mines: 1902 ... 514
Table 9.—Capitalization of incorporated companies reporting development work without production: 1902 ... 515
Incorporated companies, grouped by class of stock: 1902 ... 516
Table 10.—Authorized capitalization of incorporated companies, producing and nonproducing mines, by states and territories: 1902 and 1880 ... 516
Capitalization of dividend paying and nondividend paying companies with dividends and interest paid: 1902 ... 517
Table 11.—Summary for dividend paying and nondividend paying companies, by classes of mines: 1902 ... 517
Employees and wages ... 518–521
Table 12.—Distribution of wage-earners according to daily rates of pay, by occupations: 1902 ... 518
Table 13.—Distribution of wage-earners according to daily rates of pay, by states and territories: 1902 ... 519
Table 14.—Summary for mines worked on shares: 1902 ... 520
Table 15.—Summary for mines operated without hired labor: 1902 ... 521
Contract work ... 521
Time in operation ... 521–523
Table 16.—Number of mines, classified according to number of days in operation, by states and territories: 1902 ... 522
Table 17.—Number of mills, classified according to number of days in operation, by states and territories: 1902 ... 522
Table 18.—Number of mines and mills in the United States, classified according to number of working shifts per day, and number of hours per shift: 1902 ... 522
Table 19.—Number of mines, classified according to number of working shifts per day and number of hours per shift, by states and territories: 1902 ... 522
Table 20.—Number of mills, classified according to number of working shifts per day and number of hours per shift, by states and territories: 1902 ... 523
Supplies and materials and miscellaneous expenses ... 523, 524
Rents and royalties paid by producing mines: 1902 ... 524
Mineral lands ... 524–526
Table 21.—Classification of mines according to acreage, by states and territories: 1902 ... 524, 525
Table 22.—Classification of deep and placer mines by acreage and value of product: 1902 ... 526
Table 23.—Value of product and royalties of deep mines operating on leased land only: 1902 ... 526
Table 24.—Summary for deep mines operated on leased land only: 1902 ... 526
Mechanical power ... 526–530
Table 25.—Power used in producing mines: 1902 ... 527
Table 26.—Deep mines using hand and animal power only: 1902 ... 527
Table 27.—Placer mines using mechanical or other power: 1902 ... 527
Table 28.—Steam engines and horsepower, by states and territories: 1870 to 1902 ... 527
Table 29.—Machinery, by kinds and by states and territories: 1902 ... 528
Table 30.—Steam hoists at deep mines, by states and territories: 1902 and 1880 ... 529
Table 31.—Pumps at deep mines, by states and territories: 1902 and 1880 ... 529
Table 32.—Number of power drills at deep mines, by states and territories: 1902 and 1880 ... 529
Table 33.—Comparison of power drills and hand power at deep mines: 1902 ... 530
Water plants ... 530
Table 34.—Water plants—length of ditches, flumes, pipes, etc., by states and territories: 1902 ... 530
Production ... 530–537
Table 35.—Value of product at mine: 1902 ... 531
Bullion contents ... 532, 533
Table 36.—Bullion contents of the product of gold and silver mines, classified by character of mine: 1902 ... 533
Table 37.—Bullion contents of the product of gold and silver mines, by states and territories: 1902 ... 533
Gold and silver as by-products of other ores ... 533, 534
Table 38.—Gold and silver contents of the product of all mines: 1902 ... 533
Table 39.—Summary of mines producing argentiferous iron ore: 1902 ... 534
Table 40.—Gold and silver contents of all ores mined, by states and territories: 1902 ... 534
Comparisons with the report of the Director of the Mint ... 534–536
Precious metal contents, Bureau of the Census, and Mint returns ... 535
Table 41.—Comparative statement of the gold contents of the product mined, as reported to the Bureau of the Census, and by Mint officers and agents, by states and territories: 1902 ... 535
Table 42.—Comparative statement of the silver contents of the product mined, as reported to the Bureau of the Census, and the product of silver refineries, as estimated by the Director of the Mint, by states and territories: 1902 ... 536
Gold and silver contents of placer bullion, as reported by Mint agents: 1902 ... 536
Comparison with smelter returns ... 536, 537
Shipping and milling ores ... 537–541
Table 43.—Tonnage treated and bullion contents of ores reduced at mine and shipped in crude state: 1902 ... 538
Charges for treatment and freight ... 539
Table 44.—Treatment charges and freight on the product of mines and mills: 1902 ... 539
Table 45.—Tonnage treated at outside works, treatment charges, and freight, by states and territories: 1902 ... 539

GOLD AND SILVER—Continued.
Shipping and milling ores—Continued. Page.
Grade of ore ... 539–541
Table 46.—Gold and silver values contained in the product of precious metal mines, classified by grade of ore, by states and territories: 1902 ... 540
Table 47.—Tons of ore treated, gold and silver contents, total and average per ton, by states and territories: 1902 and 1880 ... 541
Classification of mines by metals produced ... 541, 542
Table 48.—Summary of deep mines, classified by metals produced: 1902 ... 542
Table 49.—Dividend paying productive deep mines, classified by metals produced: 1902 ... 542
Deep mines ... 542–547
Mines with and without reduction works ... 542
Table 50.—Deep mines with and without mill connection: 1902 ... 542
Arrastras ... 542, 543
Table 51.—Summary for arrastras: 1902 ... 543
Ore treated by hand ... 543
Table 52.—Summary for mines where the ore was treated in hand mortars: 1902 ... 543
Custom mills ... 543, 544
Table 53.—Summary for custom mills: 1902 ... 543
Tons of ore bought and treated for a stipulated compensation: 1902 ... 543
Mills in 1902 and 1880 ... 544
Production of mills: 1902 and 1880 ... 544
Methods of treating the ore ... 544–547
Method of treating ore, by classes of mills: 1902 ... 544
Amalgamation and concentration ... 544, 545
Table 54.—Mines and mills, with amalgamation and concentration plants: 1902 ... 545
Chlorination plants ... 545
Table 55.—Mines and mills, with chlorination plants: 1902 ... 545
Cyaniding plants ... 546
Table 56.—Mines and mills, with cyaniding plants: 1902 ... 546
Bullion contents of ore sold crude: 1902 ... 547
Reworking old dumps and tailings ... 547
Table 57.—Summary of mills operating principally on old dumps and tailings: 1902 ... 547
Placer mines ... 547–550
Table 58.—Gold product of placer mines, by states and territories: 1902 and 1880 ... 547
Methods of working ... 547–550
Products of placers, classified by method used: 1902 ... 547
Table 59.—Summary for placer mines, by method of working: 1902 ... 548
Hydraulicking ... 548
Table 60.—Summary for hydraulic mines: 1902 ... 548
Summary for hydraulic mines: 1902 and 1870 ... 548
Placer mines combined with stamp mills ... 548
Table 61.—Summary for placer mines equipped with stamp mills: 1902 ... 548
Dredging ... 548–550
Table 62.—Summary for gold mines operated by dredges: 1902 ... 549
Table 63.—Capitalization of incorporated gold dredging companies, by states and territories: 1902 ... 549
Gold dredging mineral lands owned and leased, by states and territories: 1902 ... 550
Mineral lands, classified by area held: 1902 ... 550
Tendency toward concentration ... 550–553
Table 64.—Classification of mines by value of product: 1902 ... 550
Table 65.—Custom mills, classified by value of product ... 551
Table 66.—Classification of mines and mills according to value of product, and the percentage that each group is of the total, by states and territories: 1902 ... 551
Table 67.—Classification of deep mines by metals mined and by value of product: 1902 ... 551
Table 68.—Dividend paying and nondividend paying productive mines, deep and placer, classified by value of product: 1902 ... 553
Production of gold and silver in the United States from 1889 to 1902 ... 553
Table 69.—Product of mines and refineries: 1889 to 1902 ... 553
Review of the industry by states ... 553–563
Alaska ... 555–558
Table 70.—Summary of deep mines in Alaska: 1902 ... 556

Alaska ... 681, 682
Production of coal on the Yukon river: 1897 to 1902 ... 682
Arkansas ... 682, 683
Table 19.—Coal production of Arkansas, by counties: 1902 ... 682
Table 20.—Summary by counties having a production of 200,000 tons or over: 1902 ... 683
California ... 683
Colorado ... 683, 684
Table 21.—Coal production of Colorado, by counties: 1902 ... 683
Table 22.—Summary by counties having a production of 200,000 tons or over: 1902 ... 684
Illinois ... 684, 685
Table 23.—Coal production of Illinois, by counties: 1902 ... 684
Table 24.—Summary by counties having a production of 200,000 tons or over: 1902 ... 685
Indian Territory ... 685
Indiana ... 685, 686
Table 25.—Coal production of Indiana, by counties: 1902 ... 686
Table 26.—Summary by counties having a production of 200,000 tons or over: 1902 ... 686
Iowa ... 686, 687
Table 27.—Coal production of Iowa, by counties: 1902 ... 686
Table 28.—Summary by counties having a production of 200,000 tons or over: 1902 ... 687
Kansas ... 687, 688
Table 29.—Coal production of Kansas, by counties: 1902 ... 687
Table 30.—Summary by counties having a production of 200,000 tons or over: 1902 ... 688
Kentucky ... 688, 689
Table 31.—Coal production of Kentucky, by counties: 1902 ... 689
Table 32.—Summary by counties having a production of 200,000 tons or over: 1902 ... 689
Maryland ... 690
Michigan ... 690, 691
Table 33.—Coal production of Michigan, by counties: 1902 ... 690
Table 34.—Summary by counties having a production of 200,000 tons or over: 1902 ... 691
Missouri ... 691
Table 35.—Coal production of Missouri, by counties: 1902 ... 691
Table 36.—Summary by counties having a production of 200,000 tons or over: 1902 ... 691
Montana ... 692
Table 37.—Coal production of Montana, by counties: 1902 ... 692
Table 38.—Summary by counties having a production of 200,000 tons or over: 1902 ... 692
New Mexico ... 692, 693
Table 39.—Coal production of New Mexico, by counties: 1902 ... 693
Table 40.—Summary by counties having a production of 200,000 tons or over: 1902 ... 693
North Carolina ... 693
North Dakota ... 693, 694
Table 41.—Coal production of North Dakota, by counties: 1902 ... 694
Ohio ... 694, 695
Table 42.—Coal production of Ohio, by counties: 1902 ... 694
Table 43.—Summary by counties having a production of 200,000 tons or over: 1902 ... 695
Oregon ... 695
Pennsylvania ... 695–697
Table 44.—Coal, bituminous, of Pennsylvania—production, by counties: 1902 ... 696
Table 45.—Summary by counties having a production of 200,000 tons or over: 1902 ... 697
Tennessee ... 697, 698
Table 46.—Coal production of Tennessee, by counties: 1902 ... 698
Table 47.—Summary by counties having a production of 200,000 tons or over: 1902 ... 698
Texas ... 698, 699
Table 48.—Coal production of Texas, by counties: 1902 ... 699
Utah ... 699
Table 49.—Coal production of Utah, by counties: 1902 ... 699
Table 50.—Summary by counties having a production of 200,000 tons or over: 1902 ... 699
Virginia ... 699, 700
Table 51.—Coal production of Virginia, by counties: 1902 ... 700
Table 52.—Summary by counties having a production of 200,000 tons or over: 1902 ... 700
Washington ... 700, 701
Table 53.—Coal production of Washington, by counties: 1902 ... 701
Table 54.—Summary by counties having a production of 200,000 tons or over: 1902 ... 701
West Virginia ... 701, 702
Table 55.—Coal production of West Virginia, by counties: 1902 ... 702
Table 56.—Summary by counties having a production of 200,000 tons or over: 1902 ... 702

COAL—Continued.
Bituminous—Continued.
Production by states—Continued. Page.
Wyoming ... 703
Table 57.—Coal production of Wyoming, by counties: 1902 ... 703
Table 58.—Summary by counties having a production of 200,000 tons or over: 1902 ... 703
Occurrence ... 703–705
Table 59.—Coal, Pennsylvania anthracite—detailed summary, by counties: 1902 ... 706, 707
Table 60.—Coal, bituminous—detailed summary, by states and territories: 1902 ... 709–717
PETROLEUM. By F. H. Oliphant ... 719–764
Table 1.—Comparative summary: 1860 to 1902 ... 721
Wells and tankage ... 721, 722
Table 2.—Record of wells and tankage, by states and territories: 1902 ... 722
Capital stock of incorporated companies ... 722, 723
Table 3.—Capitalization of incorporated companies: 1902 ... 722, 723
Employees and wages ... 723, 724
Table 4.—Average number of wage-earners employed during each month: 1902 ... 723
Table 5.—Average number of wage-earners at specified daily rates of pay, by occupations: 1902 ... 724
Contract work ... 724
Supplies, materials, and miscellaneous expenses ... 724
Mechanical power ... 724
Production ... 724, 725
Table 6.—Quantity and value, with percentages, by states and territories: 1902 ... 725
Table 7.—Production, value, and average price per barrel, by states and territories, and by districts: 1902 and 1901 ... 725
Petroleum and natural gas ... 725, 726
Table 8.—Value of petroleum and natural gas: 1902 ... 726
Exports ... 726–729
Table 9.—Production and exports of crude and manufactured products: 1864 to 1902 ... 726, 727
Table 10.—Exports of petroleum in its various forms from the United States, by countries, for the fiscal years 1894 to 1902 ... 727, 728
Table 11.—Exports of petroleum and petroleum products to Europe, North and South America, Asia and Oceania, and Africa, with percentages for the fiscal year ending June 30, 1902 ... 729
Prices ... 729
Average yearly prices per gallon of refined petroleum: 1892 to 1902 ... 729
Table 12.—Monthly average prices per gallon of oil exported from the United States in bulk: 1899 to 1902 ... 729
Production in the United States since 1859 ... 729–731
Table 13.—Production, by states and territories: 1859 to 1902 ... 730
Table 14.—Quantity and value of production: 1859 to 1902 ... 731
Review of the industry by fields ... 731–737
Table 15.—Production, by fields and states: 1889 to 1902 ... 731
Per cent of total crude petroleum produced in the several fields: 1896 to 1902 ... 732
Appalachian field ... 732, 733
Table 16.—Production of petroleum in the Appalachian oil field, by states: 1889 to 1902 ... 732
Table 17.—Total number of wells completed in the Appalachian oil field, by districts: 1892 to 1902 ... 733
Table 18.—Well record in the Appalachian oil field: 1902 ... 733
Appalachian, Lima-Indiana, and all other fields ... 733–737
Table 19.—Production of petroleum in the Appalachian, Lima-Indiana, and all other fields, percentages of each, value per barrel, and the value of petroleum and natural gas, separate and combined: 1896 to 1902 ... 733
Table 20.—Production and value of natural lubricating petroleum, by states and districts: 1896 to 1902 ... 734
Table 21.—Pipe line runs in the Appalachian field, in detail: 1888 to 1902 ... 734
Table 22.—Totals of pipe line runs in the Appalachian and Lima-Indiana fields: 1888 to 1902 ... 735
Table 23.—Shipments in the Appalachian and Lima-Indiana fields: 1894 to 1902 ... 735
Table 24.—Stocks of petroleum in the Appalachian and Lima-Indiana fields at the close of the year: 1894 to 1902 ... 735
Table 25.—Stocks of petroleum held in the several fields, states, and territories at the close of 1902, 1901, and 1900 ... 735
Table 26.—Average yearly price of all the petroleum produced: 1889 to 1902 ... 736
Table 27.—Range of prices paid for petroleum in the Appalachian oil region by the Seep Purchasing Agency during 1902 ... 736
Table 28.—Average monthly prices of Appalachian crude petroleum: 1902 and 1901 ... 736
Table 29.—Average monthly prices of Ohio and Indiana crude petroleum: 1902 and 1901 ... 736
Table 30.—Fluctuations in prices of Lima (Ohio) and Indiana crude petroleum: 1902 ... 737
Table 31.—Highest, lowest, and average prices of Lima (Ohio) crude petroleum: 1887 to 1902 ... 737
Review of the industry by states and territories ... 737–748
Alaska ... 737
Log of well east of Catella bay, Kayak district, drilled in 1902 ... 737
California ... 737–739
Table 32.—Production of crude petroleum in California, by counties: 1897 to 1902 ... 739
Colorado ... 739
Illinois ... 739, 740

NATURAL GAS. By F. H. Oliphant 765–781
Table 1.—Comparative summary: 1902 and 1889 767
Table 2.—Value of natural gas produced, record of wells, and length of pipe laid, by states: 1902 768
Capital stock of incorporated companies 768
Table 3.—Capitalization of incorporated companies: 1902 768
Employees and wages 768, 769
Table 4.—Average number of wage-earners employed during each month: 1902 769
Table 5.—Average number of wage-earners at specified daily rates of pay: 1902 769
Contract work 769
Supplies, materials, and miscellaneous expenses 769
Mechanical power 769, 770
Production 770, 771
Table 6.—Value of production of natural gas: 1872 to 1902 770
Table 7.—Value of natural gas produced and consumed, by states: 1899 to 1902 771
Descriptive 771–776
Occurrence 771–773
Historical 773, 774
Uses 774, 775
The measurement of the output of gas wells 775
Compressors 775
The natural gas engine 775, 776
Distribution of natural gas to the consumer 776
Table 8.—Detailed summary: 1902 778–781
STONE. By George P. Merrill, Ph. D 783–835
Table 1.—Comparative summary: 1880 to 1902 785
Capital stock of incorporated companies 785, 786
Table 2.—Capitalization of incorporated companies: 1902 785
Table 3.—Operators by value of product: 1902 786
Employees and wages 786, 787
Table 4.—Average number of wage-earners employed during each month: 1902 786
Table 5.—Distribution of wage-earners according to daily rates of pay, by occupations: 1902 787
Supplies, materials, and miscellaneous expenses 787
Mechanical power 787, 788
Production 788
Table 6.—Value of annual production of stone: 1890 to 1902 788
Classification and occurrence 788, 789
Limestones and dolomites 788
Marble 788
Sandstones and quartzites 788
Silica sand 788
Siliceous crystalline rocks 788
Slate 788
Occurrence 788, 789
Limestones and dolomites 789–791
Table 7.—Comparative summary: 1902 and 1889 789
Employees and wages 789, 790
Table 8.—Average number of wage-earners employed during each month: 1902 790
Table 9.—Distribution of wage-earners according to daily rates of pay, by occupations: 1902 790
Supplies, materials, and miscellaneous expenses 790
Mechanical power 790
Production 790, 791
Table 10.—Value of annual production of limestones and dolomites: 1890 to 1902 791
Table 11.—Limestones and dolomites, classified by uses: 1894 to 1902 791
Occurrence 791
Marble 791–795

ASPHALTUM AND BITUMINOUS ROCK. By Joseph Struthers, Ph. D 975–985
Table 1.—Comparative summary: 1860 to 1902 977
Development work: 1902 978
Capital stock of incorporated companies 978
Table 2.—Capitalization of incorporated companies: 1902 978
Employees and wages 978
Supplies, materials, and miscellaneous expenses 978
Mechanical power 978, 979
Production 979
Table 3.—Crude asphaltum imported for immediate consumption: 1889 to 1902 979
Table 4.—Production of asphaltum in principal producing countries: 1890 to 1901 979
Descriptive 979–984
Physical and chemical characteristics 980, 981
Analyses of pure asphaltum, exclusive of earthy matter and other mechanical impurities 980
Analyses of representative asphaltic limestones, showing their general composition 981
Occurrence 981, 982
Arkansas 982
California 982
Indian Territory 982, 983
Kentucky 983
Texas 983
Utah 983
Uses 983, 984
Asphaltum refining 984
Table 5.—Detailed summary: 1902 985
BAUXITE. By Joseph Struthers, Ph. D 987–993
Table 1.—Summary: 1902 989
Capital stock of incorporated companies 989
Employees and wages 989
Supplies, materials, and miscellaneous expenses 990
Mechanical power 990
Production 990, 991
Table 2.—Production, imports, exports, and consumption of bauxite and the production and value of aluminum, 1889 to 1902, and of alum and aluminum sulphate, 1889 to 1902 990
Table 3.—World's production of bauxite: 1900 and 1901 990
Descriptive 991–993
Occurrence 991
Analyses of specimens of bauxite from various countries 992
Chemical properties 992
Physical properties 992
Important products derived from bauxite 992, 993
Aluminum sulphate 992, 993
Potassium alum 993
Aluminum hydroxide 993
Artificial emery 993

MINERAL INDUSTRIES OF PORTO RICO. By William F. Willoughby 1073–1085
Map showing location 1074
Mining laws 1077
Precious metals 1078
Registered mining claims of precious metals 1078
Placer gold mining 1078
Base metals 1078, 1079
Registered mining claims of base metals 1079

MINERAL INDUSTRIES OF PORTO RICO—Continued.
Page.
Salt 1079, 1080
Production of salt: 1902 1080
Clay products 1080, 1081
Clay products: 1902 1080
Limestone 1081–1083
Production of limestone: 1902 ..... 1082, 1083
Phosphate rock 1083, 1084
Registered mining claims of phosphate rock 1083
Unregistered mining claims of phosphate rock 1084
Granite 1084
Mineral springs 1084, 1085

APPENDICES.

APPENDIX A.—Schedules 1089–1105
APPENDIX B.—Instructions to special agents 1107–1112
APPENDIX C.—Instructions for editing and revising the schedules 1113–1123

DIAGRAMS AND ILLUSTRATIONS.

General:
Diagram I.—Value of products of principal minerals and proportion each bears to total: 1902 43
Diagram II.—Production of principal minerals, by states and territories: 1902 ..... 46, 47
Diagram III.—Value of all mineral products and value of each group: 1902 49
Diagram IV.—Production of principal minerals: 1902 49
Diagram V.—Value per square mile of minerals produced, by states and territories: 1902 49
Diagram VI.—Value of minerals produced in each state and territory: 1902 53
Diagram VII.—Proportion of minerals produced by geographic divisions: 1902 53
Electricity in mining:
Plate I.—Long distance electric transmission in California 146
Plate II.—Electric coal cutter 150
Plate III.—Electric coal cutter 150
Plate IV.—Electric drill at work in a mine 152
Plate V.—Trolley electric locomotive in coal mine 154
Plate VI.—Electric mine locomotive with reel of wire for flexible connection to circuit 154
Plate VII.—Two 250-volt electric locomotives in coal mines at Kingston, Pennsylvania 154
Plate VIII.—Electric locomotive, with reel for an extension cable 154
Plate IX.—Mine pump, driven by a 150-horsepower motor 156
Plate X.—Four-stage mine pump, driven by a 150-horsepower motor 156
Plate XI.—Electric gold dredger at work in California 160
Iron ore:
Plate I.—Pioneer and Chandler mines at Ely, Minnesota 398
Plate II.—Auburn mine milling pit, Mesabi Range, Minnesota 400
Plate III.—No. 2 pit, Adams mine, Eveleth, Minnesota 402
Plate IV.—Steel shaft house, Adams mine, first on the Mesabi Range 402
Plate V.—Mount Iron mine, Mesabi Range, looking east across pit, showing two stripping and three ore levels 404
Plate VI.—Group of mine buildings and dwellings, Cliffs Shaft mine, Lake Bancroft, Michigan 406
Plate VII.—Cleveland Lake mine, Marquette Range, Michigan, looking east 408
Plate VIII.—Cliffs Shaft mine, Marquette Range, Michigan 410
Plate IX.—The Salisbury mine, Marquette Range, Michigan 412
Plate X.—Red hematite mine, Red Mountain, near Birmingham, Alabama 414
Plate XI.—Limonite banks near Tecumseh, Cherokee county, Alabama 414
Plate XII.—View of No. 21 mine, Port Henry Iron Company, Mineville, near Port Henry, New York 416
Plate XIII.—Cut in Middle Hill, Cornwall ore banks, Cornwall, Lebanon county, Pennsylvania 416
Plate XIV.—Sunrise pit from the east, at Sunrise, Laramie county, Wyoming 418
Plate XV.—Nos. 3 and 4 trams and railroad tracks, Orient mine, near Salida, Saguache county, Colorado 418
Diagram I.—Classification of iron ore production: 1889 to 1902 420
Diagram II.—Production of iron ores in the United States: 1902, 1889, and 1880 422
Diagram III.—Annual production of iron ore in the United States 424
Diagram IV.—Contemporaneous production of iron ores in the United States, Great Britain, and Germany; also relative proportion supplied from the Lake Superior region: 1889 to 1902 425
Copper:
Diagram I.—Average prices of copper, New York and London: 1879 to 1902 497
Diagram II.—Production, consumption, and exports of copper in the United States: 1895 to 1902 499
Diagram IIA.—Average New York prices of copper: 1895 to 1902 499
Diagram III.—European demand for imported copper: 1895 to 1902 501
Diagram IV.—Consumption of imported copper in Great Britain, imports from the United States and other countries: 1895 to 1902 502
Diagram IVA.—Average London prices of copper: 1895 to 1902 502
Diagram V.—Consumption of copper in France: 1895 to 1902 503
Diagram VI.—Consumption of copper in Germany: 1895 to 1902 503

Page.

Gold and silver:
Diagram I.—Production of gold from 1889 to 1902 in the states and territories reporting more than 50,000 ounces in 1902 ... 552
Diagram II.—Production of silver from 1889 to 1902 in the states reporting more than 2,500,000 ounces in 1902 ... 554
Diagram III.—Production of gold: 1889 to 1902 ... 556
Diagram IV.—Production of silver: 1889 to 1902 ... 558
Diagram V.—Variation of the commercial ratio of silver to gold since 1700 ... 569
Diagram VI.—Prices of silver and lead in the London market: 1843 to 1872 ... 570
Diagram VII.—Prices of silver and lead in the London market, and lead prices in the New York market: 1873 to 1902 ... 570
Plate I.—Gold dredge, driven by electric power ... 572
Plate II.—Vein in 1,200-foot level, Daly-Judge mine, Park City, Utah ... 574
Plate III.—Stope, west drift, 2,000 feet from line, Anchor mine, near Park City, Utah ... 574
Plate IV.—Interior of mill of the United Gold Mining, Milling and Tunnel Company, Idaho Springs, Colorado ... 576
Cyanide processes:
Plate I.—Eureka cyanide plant near Carson City, Nevada ... 578
Coal:
Diagram I.—Production of coal per capita, and comparison of population with production: 1830 to 1902 ... 670
Diagram II.—Domestic production and consumption of coal, 1902, and coal production of the world: 1902, 1890, 1880, and 1870 ... 672
Stone:
Plate I.—Quarry in oolitic limestone, Bedford, Indiana ... 786
Plate II.—General view of stone yards and works of the Vermont Marble Company, Proctor, Vermont ... 788
Plate III.—Interior view of marble quarry, Proctor, Vermont ... 790
Plate IV.—Interior view of marble quarry, Rutland, Vermont ... 792
Plate V.—Interior view of marble quarry near Tate, Pickens county, Georgia ... 794
Plate VI.—Fig. 1—View near western end of Great Canyon sandstone quarry, Amherst, Ohio ... 796
Fig. 2—View of sandstone quarry at Berea, Ohio ... 796

U. S.
WASHINGTON, D. C.

LETTER OF TRANSMITTAL.

DEPARTMENT OF COMMERCE AND LABOR,
BUREAU OF THE CENSUS,
Washington, D. C., July 7, 1904.

SIR:

I have the honor to transmit herewith a report on mines and quarries and petroleum and natural-gas wells for the year ending December 31, 1902. This report contains the statistics of the Twelfth Census of the mining industries of the United States. At all prior censuses the mining industries have been enumerated at the same time as the population, manufactures, and agriculture, but the date of the enumeration was changed by the act of Congress of March 6, 1902, which provides that the statistics relating to mines, mining, quarries, and minerals, should be collected decennially after the completion and return of the enumeration and of the work upon the schedules relating to the products of agriculture and to manufacturing and mechanical establishments.

The mining census was conducted in collaboration with the United States Geological Survey, the statistics being collected in connection with the data required for the annual report of the mineral resources of the United States. The objects of this collaboration were to avoid duplication of the fieldwork and the necessity of calling on the mine operators for duplicate reports; also to obtain harmonious results for the two offices. The totals for the two offices agree, with the exception of a few minerals, for which the Geological Survey includes manufacturing processes carried on entirely distinct from the mining operations, and in some instances where that office calls for the product marketed or sold instead of that produced during the year.

Mining industries are frequently carried on by establishments engaged in both mining and manufacturing, and for statistical purposes it is often impossible to separate the operations. The report on manufactures for the Twelfth Census includes the statistics for all products that could be considered as the results of manufacturing processes, and such products have, as far as possible, been excluded from this report. It would add to the value of these statistics if the mining and manufacturing industries were covered by the same enumeration and the total presented as the manufacturing and mechanical industries of the country. Under the existing law it is impossible to compile such a total for the same year for all branches of industry.

This report has been prepared in the division of manufactures, under the supervision of Mr. William M. Steuart, chief statistician for manufactures, assisted by Mr. Joseph D. Lewis, chief of division. I desire also to acknowledge the services of the efficient force of the Geological Survey that worked under the supervision of Dr. David T. Day, chief of the division of mining and mineral resources, and of Mr. William A. Countryman, of this Bureau, who assisted in the preparation of the textual discussion.

Very respectfully,

S. N. D. North

Director.

Hon. VICTOR H. METCALF,
Secretary of Commerce and Labor.

MINES AND QUARRIES.

CHAPTER I.

PLAN AND SCOPE OF INQUIRY.

I.

PROVISIONS OF LAW.

The First Census of the United States, taken in 1790 by the United States marshals and their assistants, contained no statistics relative to manufacturing or mining industries, being confined to an enumeration of the inhabitants or population of the country. The Second Census, taken in 1800, was practically the same in scope. The first attempt to collect any industrial statistics was made in connection with the Third Census, under the provisions of a special amendatory act, passed May 1, 1810, which required the "marshals' secretaries and their assistants * * * to take * * * an account of * * * manufacturing establishments and manufactures." From the digest of these statistics, prepared by Tench Coxe under the direction of the Secretary of the Treasury, it appears that the schedule secured information concerning the cutting and dressing of marble, slate, and other stones, the quarrying of slate, the mining of saltpeter, and the production of red and yellow ocher, but that no reference was made to minerals from which metallic substances are derived save in the classification "lead and manufactures of lead." There was included under this classification the substance known as black lead (graphite). Although the law providing for the census of 1820 contained a provision similar to that of the law of 1810 concerning industrial statistics, there is no evidence that statistics of mines and quarries were taken. The section concerning industrial statistics was omitted from the law providing for the census of 1830.

No further attempt appears to have been made to collect statistics for mines and quarries until the census of 1840, which was taken in conformity with the act of March 3, 1839. This was the first census law to contain a specific provision for the collection of statistics of mines. Section 13 of the law provided that "the aforesaid marshals and their assistants * * * also shall collect and return in statistical tables under proper heads, according to such forms as shall be furnished, all such information relating to mines, agriculture, commerce, manufactures, and schools as will exhibit a full view of the pursuits, industry, education, and resources of the country * * *."

The Seventh, Eighth, and Ninth censuses were taken under the act of May 23, 1850, which authorized not only the enumeration of all inhabitants, but also the collection of "all the other statistical information * * * specified in the instructions which shall be given by the Secretary of the Interior and in the tables annexed." Under this provision statistics of mines continued to be taken, but only in a scattering way and in connection with other statistics until the census of 1870, when they were given separately and with comparative fullness.

Section 18 of the act of March 3, 1879, providing for the census of 1880, contains the following provision: "And said Superintendent may employ experts and special agents to investigate in their economic relations the manufacturing, railroad, fishing, mining, and other industries of the country * * *." The form of the inquiries concerning mining and other productive industries was left to the discretion of the Superintendent of the Census and the Secretary of the Interior.

The only direct reference to a mining census that is made in the act of March 1, 1889, which provided for the Eleventh Census is contained in section 17. This section provided that the only volumes to be published in connection with that census were those relating to population and social statistics, manufactures, mining, agriculture, mortality and vital statistics, valuation and public indebtedness, recorded indebtedness, and statistics relating to railroad corporations and incorporated express, telegraph, and insurance companies. But among the reports which the Superintendent was "required to obtain," if directed to do so by the Secretary of the Interior, were those "from all corporations or establishments reporting products other than agricultural products."

30223—04——1

The act of March 3, 1899, providing for the Twelfth Census, was the first census law to describe the scope of the mining census and to make a definite line of demarcation between the statistics of mines and those of manufactures. Section 8 provides "that after the completion and return of the enumeration and of the work upon the schedules relating to the products of agriculture and to manufacturing * * * the Director of the Census is hereby authorized to collect statistics relating to * * * mines, mining, and minerals, and the production and value thereof, including gold in divisions of placer and vein, and silver mines, and the number of men employed, the average daily wage, average working time, and aggregate earnings in the various branches and aforesaid divisions of the mining industry * * *." Before the reports on population, agriculture, and manufactures were completed the act of March 6, 1902, providing for the establishment of a permanent Census Office, became a law, and it was therefore in conformity with this law rather than that of March 3, 1899, that the census of mines and quarries of 1902 was taken. No material change was made, however, in the provisions of section 8, cited above.

At all censuses prior to the Twelfth the statistics of mines and quarries, whenever taken, were collected in connection with the statistics of population, agriculture, and manufactures, and were published as a part of the regular census reports. This practice is correct from both a theoretical and a practical point of view. The separation for the census of 1900 was made apparently because the work incident to the mining census might have tended to delay the completion of the reports on the other more important subjects. It is a distinct advantage, however, to have the reports on agriculture, manufactures, and mining cover the same, or practically the same, period, as it is thus made possible to present statistics of all branches of productive industry for the same year. Under the present law and practice the year covered by the mining census does not expire until more than two and one-half years after the close of that covered by the other industrial statistics—one being the calendar year, and the other the year ending June 1—therefore the reports for the mining census can not be published until about four years after the census year covered by the statistics of manufactures and agriculture. The period covered by the present mining census is the year ending December 31, 1902, and the conditions prevailing during that year in some branches of mining differed materially from those that prevailed during the census year ending June 1, 1900. This difference is especially noticeable in the anthracite coal industry, where the mining operations were practically suspended for six months, although they were in full operation during the entire year covered by the census of 1900. Still, in order to show totals for the mechanical, manufacturing, and mining industries, the statistics for these two dissimilar years must be combined, though the totals are a combination of statistics that represent a prosperous condition for manufactures and a depressed condition in one important branch of mining. The combination, therefore, is not indicative of the results of a year's work under either condition. The office was cognizant of these objections to a mining census covering the year 1902 and the advisability of such a census was carefully canvassed. After much consideration Mr. S. N. D. North, who then held the position of chief statistician for manufactures, sent the following letter of recommendation to the Director of the Census:

OCTOBER 11, 1902.

HON. WILLIAM R. MERRIAM,
Director of the Census.

DEAR SIR: In accordance with your verbal instructions I have consulted with a number of people, including Colonel Wright, Commissioner of Labor, and Mr. Walcott, Director of the Geological Survey, in regard to the advisability of making a census of the mining industry as of the year 1902, in view of the fact that the coal strike in the anthracite regions has produced conditions so abnormal in that branch of the mining industry that a census taken as of the year in which the strike occurred would result in data misleading and unsatisfactory.

It is the judgment of all the gentlemen with whom I have consulted that the fact of the anthracite coal strike does not constitute a good and sufficient reason for postponing the census mining inquiry, and in this judgment I concur. It is the opinion of Mr. Walcott that the statistics of anthracite coal mining can be taken as of the year 1901 so far as quantities and values are concerned. It is suggested by Commissioner Wright that statistics of the anthracite coal mining industry, taken as of the year 1901, so far as quantities and values are concerned, and as of the year 1902, so far as relates to other items, will prove of great value in the immediate future in connection with the discussion of the controversy which has arisen between the coal operators and the coal miners of the anthracite region, and that Congress and the people of the United States ought to have the benefit of such statistics in view of important economic questions arising from the strike in question. Colonel Wright also suggests that certain questions having a direct bearing upon the existing situation in the anthracite coal region may with propriety be added to the special schedule adopted for that branch of the mining industry.

I therefore recommend that the division of manufactures shall continue and perfect its plans for taking a mining census as of the present calendar year, with a view to the commencement of field-work early in the year 1903.

Such a course was undoubtedly contemplated by Congress in the passage of the act providing for a permanent Census Office, approved March 6, 1902. It is true that the portion of section 7 of the act in question which undertakes to fix the date for the mining census is difficult of intelligent interpretation in the form in which it was enacted, but an examination of the debate in the House of Representatives at the time when the words "until July first, nineteen hundred and four," were inserted in the bill in the form of an amendment offered by Mr. Williams, of Mississippi, reveals the fact that the purpose of these words was to restrict the Census Office to a single report upon the mining industry and to exclude annual reports, and that it was intended that this should be taken and published prior to the date named. In order to comply literally with the intent of Congress, as revealed in the debates of the House in connection with this amendment, it will be necessary to take the mining census as of the calendar year 1902.

With reference to the plans for the mining census, I respectfully recommend that the inquiry be divided into three parts, as follows: Part 1, Precious metals; Part 2, Stone quarrying of all descriptions; Part 3, All other minerals, metallic and nonmetallic.

I also recommend that the details of the work for each part shall be under the immediate direction and within the complete control of the chief statistician for manufactures and his assistants.

I recommend the appointment of Mr. I. A. Hourwich, of Washington, D. C., as consulting expert special agent for the precious metals, at a compensation of $6 per diem when actually employed. Mr. Hourwich was formerly connected with the Treasury Bureau of the Mint and is highly recommended by Director George E. Roberts. I make this recommendation with the understanding that Mr. Hourwich is to have access to all the records and data of the Mint in connection with this work, and that the Census Office is to have the benefit of the cooperation of that bureau of the Government as the result of Mr. Hourwich's appointment.

For the second branch of the inquiry I recommend the appointment of Mr. George P. Merrill as consulting expert special agent. Mr. Merrill is one of the head curators of the National Museum, and this recommendation is made with the understanding that he will serve the Census Office without compensation, and that the office is to have the benefit of all the records and data of the National Museum so far as they relate to the stone quarrying industries of the United States.

For the third branch of the mining inquiry I recommend that a consulting expert special agent be appointed who shall be mutually agreed upon by the Director of the Census and the Director of the United States Geological Survey, and with the understanding that the Census Office is to have the use and benefit of the records and data of the statistical division of the Geological Survey in the prosecution of its work, in accordance with section 28 of the act of March 3, 1899, under such conditions as shall prove satisfactory to the Director of the Geological Survey and shall be mutually agreed upon.

I am of the opinion that it will be for the benefit of the Government if the mining statistics annually collected and published by the Geological Survey are collected for the year 1902 by the Survey and the Census Office, working in conjunction and cooperation with each other, thus avoiding a duplication of governmental statistical work, the whole expense of the inquiry for that year to be borne by the Census Office; and the Geological Survey to have the benefit and use of the statistics, so far as it may require them, contemporaneously with their use and publication by the Census Office.

The details of this plan, if it can be carried out, must necessarily be the result of consultation with the Director of the Geological Survey, and must include such arrangements regarding the clerks of the Survey employed in its statistical division and their payment during the period of the inquiry as may be mutually agreed upon.

All of which is respectfully submitted.

S. N. D. North,
Chief Statistician for Manufactures.

The recommendations contained in this letter were approved, and preparations were immediately made for the mining census. These consisted of making ready the schedules and instructions, perfecting the details for cooperative work with the Geological Survey, getting together lists of mines and quarries, districting the entire country, and appointing special agents. Each of these stages of the work is explained at length under its appropriate title.

II.

DEVELOPMENT OF MINING STATISTICS.

Scope of the inquiry.—The census of 1840 was the first, except for the fragmentary information collated in 1810, to include statistics of mining and quarrying. Statistics were shown of capital, employees, and product—in combination, however, with the manufactures of the metal or mineral in each case—for coal, anthracite and bituminous; gold; granite, marble, and other stone; iron ore; and lead.

In 1850 and 1860 statistics for mines and quarries were included with those for manufactures. The first separate census of mines and quarries was in 1870; then followed the censuses of 1880 and 1890. Table 1 shows the character of the inquiries concerning mines and quarries from 1850 to 1902, as far as they are disclosed by the published results.

The subjects presented from 1850 to 1902 are shown in Table 2, which makes very plain the development in this respect during the little more than a half century which has elapsed.

TABLE 1.—CHARACTER OF INQUIRIES CONCERNING MINES AND QUARRIES: 1850 TO 1902.

	1850	1860	1870	1880	1890	1902
Number of establishments	×	×	×			
Number of mines				×	×	×
Number of operators						×
Capital						
Capital, by classes				×		
Capitalization, etc., of incorporated companies						×
Wage-earners, by sex						
Wage-earners, classified as men and boys, above and below ground				×		
Wage-earners, by occupation				×		
Wage-earners (men and boys, above and below ground), by occupation					×	×
Average number of wage-earners (men and boys) employed during each month						×
Wage-earners (men and boys), by occupation and daily rates of pay						×
Wages, total			×	×		
Wages, by sex, of wage-earners	×	×				
Wages of men and boys, above and below ground, by occupation					×	×
Cost of supplies and materials	×		×	×	×	×
Product, value	×	×	×	×	×	×
Product, quantity			×	×	×	×

		Scythestones		×		×		
		Scythe rifles		×				
		Hones and whetstones [1]			×			
		Shoemaker's sandstone				×		
		Oilstones, whetstones, and scythestones ("whetstones" in 1890)					×	
	Chemicals	Sulphur					×	
		Pyrite ("pyrites" in 1890)				×	×	
		Sulphur and pyrite						
	Pigments	Barytes		×	×	×	×	
	Miscellaneous	Asphaltum and bituminous rock ("asphaltum" prior to 1902)		×	×	×	×	
		Graphite ("plumbago, black and silver lead" in 1860)		×		×	×	
		Magnesite ("magnesia" in 1860)						
		Silica sand ("glass sand" in 1860 and 1880; "silex" in 1870)		×	×	×		×
		Soapstone				×		
		Talc					×	
		Talc and soapstone ("soapstone" in 1890)						
1870	Fuels	Peat (cut)						
	Abrasives	Garnet						
		Infusorial earth				×		×
		Infusorial earth, tripoli, and pumice						
	Chemicals	Borax [1]						
1880		Phosphate rock ("phosphates" in 1890) [1]				×	×	
	Miscellaneous	Asbestos					×	
		Mineral soap				×		
		Quartz and feldspar						
		Flint						
		Feldspar						
	Metallic	Aluminum						
		Antimony					×	
		Platinum					×	
		Tin					×	
1890	Fuels	Natural gas					×	
	Chemicals	Fluorspar					×	
	Miscellaneous	Lithographic stone					×	
		Marl					×	
		Ozocerite					×	
		Precious stones					×	
	Abrasives	Crystalline quartz						
1902	Miscellaneous	Bauxite						
		Fuller's earth						
		Lithium ore						
		Molybdenum						
		Monazite						
		Rutile						
		Tungsten						
		Uranium and vanadium						

[1] For comparative purposes considered as mining and quarrying. [2] Included with "quicksilver;" production reported separately. [3] Production only.

The census of 1850 was the first at which a complete enumeration of industrial establishments was attempted. It was also the first at which answers were required to definite questions concerning capital, labor, materials, and products, but at this and the census of 1860 the statistics for mines and quarries were subsidiary to those for manufactures, the enumeration being made by the same agencies and the statistics included in the same tables. At the census of 1870 the statistics of mining were presented separately. The defects incident to the collection of statistics for manufactures were intensified in those for mining. It was impossible for the United States marshals and their assistants to make a complete enumeration of mines and quarries, many of which were in remote localities and the schedules used were not in proper form to secure satisfactory information from the mines and quarries that were reported.

The following comparative table is introduced to show the character of the statistics reported for mines and quarries at prior censuses and to illustrate the absence of comparative data on any phase of the industry other than possibly the quantity and value of products. The figures for 1889 in this table do not agree with those in Table 4 for the reason that certain industries not considered mining have been eliminated in order to make the totals comparable; nor do they agree with those in Table 1 of Chapter II because they include only the minerals contained in the body of the report of the Eleventh Census.

TABLE 3.—MINING STATISTICS REPORTED AT CENSUSES: 1850 TO 1902.

	1902	1889	1880	1870	1860	1850
Number of mines or quarries	151,516	59,204	[1] 22,404	[2] 8,775	[2] 9,323	[2] 3,261
Number of operators	46,858					
Capital	[3]	$1,287,709,840	$1,448,808,032	$245,757,606	$65,853,730	$16,750,766
Salaried officials, clerks, etc.:						
Number	38,128	6,120	[4]	[4]	[4]	[4]
Salaries	$39,020,552	$4,724,392	[4]	[4]	[4]	[4]
Wage-earners:						
Average number	581,728	[5] 523,710	295,991	163,185	[6] 100,754	[7] 34,209
Total wages	$369,959,960	[5] $212,676,848	[8] $94,771,944	$79,430,551	$39,830,010	$12,266,236
Above ground—						
Men 16 years and over	215,286	210,964	116,792	74,684	[4]	[4]
Boys under 16 years	6,219	20,869	15,633	7,256	[4]	[4]
Below ground—						
Men 16 years and over	354,585	281,841	153,838	77,232	[4]	[4]
Boys under 16 years	5,638	10,036	9,728	4,013	[4]	[4]
Contract work	$20,677,938	$6,719,531	[3]	[3]	[3]	[3]
Miscellaneous expenses	$71,771,713	$30,236,132	[3]	[3]	[3]	[3]
Cost of supplies and materials	$123,814,967	$74,288,181	$31,447,488	$41,839,820	$25,154,924	$5,049,841
Value of products	$796,826,417	$410,760,770	$251,967,055	$191,002,543	$89,544,435	$29,826,699

[1] Mines, quarries, wells, and establishments.
[2] Establishments.
[3] Not reported.
[4] Not reported separately.
[5] Includes foremen and their wages.
[6] Includes 173 "female hands."
[7] Includes 130 "female hands."
[8] No wages were given for wage-earners in stone quarries.

The number of minerals for which statistics were shown at the census of 1860 would indicate that about all branches of mining followed at that time were included. It is impossible, at this late day, to determine the degree of completeness obtained in the statistics of minerals and mining operations collected at the censuses of 1850 and 1860. It is certain, however, that there was a great deficiency in the 1860 statistics of iron ore. The following statement appears in the Report on Manufactures for 1860, page clxxvii: "Many of the large iron works of the country either own or farm the mineral lands and mine their own ore, which is not included in the foregoing product. The quantity thus raised in 1860 amounted to about 2,309,975 tons, which, added to the product of regular mining establishments, makes the total quantity raised in 1860, 3,218,275 tons. At an average cost price of $2.40 per ton the total value would be $7,723,860." This indicates that more than two-thirds of the iron ore mining operations were omitted from the enumeration, but it is probable that they were included with the statistics of blast furnaces.

Census of 1870.—In 1870 the statistics for the mining industries were presented separately from those for manufactures. Totals were shown for the United States and for each state and territory, also for each mineral in each state by counties. The statistics were accompanied by a short explanatory text, which declared that they were entirely inadequate and fell far short of the total production. At 1870 and prior censuses the statistics, whether for mines, manufactures, or fisheries, were all collected upon a schedule having the same form. The scope of the inquiry was thus necessarily limited. The census of 1870 was supposed to cover all mines and quarries as it did manufactures, but mines and quarries where the annual production did not exceed $500 were not taken. The separation between the mining and manufacturing industries, first attempted at this census, appears to have been made with the intention of including under manufactures all work on the ore after its delivery at the mouth of the mine.

In presenting the statistics Hon. Francis A. Walker, Superintendent of the Census, stated that "the statistics following are of very unequal value, for the reason that the machinery of enumeration provided by the census law of 1850 was created without consideration of certain of the great mining industries of the country, * * * and can not be applied to them with any degree of success. It may fairly be taken for granted that an attempt to enumerate cotton spinning, coal mining, and cod fishing on one and the same schedule will always result in returns unsatisfactory in respect to one if not two of the three industries so widely diverse in character and conditions."[1]

With regard to the statistics for the precious metals Superintendent Walker says: "The statistics of the gold and silver product, as obtained by the census, are here published in conformity with what is understood to be the requirement of law; but it would be wholly unjustifiable were the figures to be put forth without a distinct and emphatic disclaimer of their validity and authority."[2]

Census of 1880.—The incomplete and defective character of the statistics at the census of 1870 and prior censuses led to the adoption of entirely different methods at the census of 1880. The scope of the inquiry was greatly extended, special schedules were introduced, and the conduct of the canvass and the compilation of the statistics were assigned to experts selected from the force of the United States Geological Survey. The inquiry not only covered the occurrence of minerals, employees and wages, and details as to the quantity and value of the different products, but extended to an analysis of the different leading minerals and the collection of numerous specimens. The report included

[1] Ninth Census of the United States, Industry and Wealth, page 748.
[2] Ibid., page 750.

statistics for manufacturing processes, such as lead, zinc, and copper smelting and refining, the refining of precious metals, and of petroleum. A directory of mines and metallurgical establishments was also included in the report. The purpose of the inquiry, as stated in the Instructions to Special Agents, was "to elucidate as far as practicable, the character, extent, and total influence of the mining industry. No industry has ever been examined throughout an extensive region so fundamentally and minutely as it is intended that the mineral industry of the West shall have been when this inquiry is successfully accomplished. The results will be a great addition to the data of political economy and will form a systematic accumulation of technical facts, such as does not at present exist."[1]

The subjects covered by the schedules for the precious metals are as follows:

Metallic mines.
Hydraulic mines.
Hydraulic ditches.
Ore-dressing works.
Amalgamating mills.
Stamp batteries.
Pan amalgamation.
Roasting furnaces in amalgamating works.
Alternate amalgamation and concentration of battery sands.
Alternate concentration and amalgamation of battery sands.
Arrastras.
Smelting works in general:
- Preliminary operations.
- Smelting in shaft furnaces.
- Smelting in reverberatory furnaces.
- Desilverization by zinc.
- Pattinsonizing.
- Improving of lead.
- Cupellation.

In addition to the above, special schedules were provided for copper, iron, and lead and zinc mines, and quicksilver production; coal mines, farmers' coal diggings, petroleum wells, slate and stone quarries, charcoal burning, and minor minerals.

All mines were included, irrespective of the value of their products, and the irregular workings were enumerated. The census, so far as it related to precious metals, was limited to mines which showed at least 200 feet of shafts and galleries or which produced 50 tons or more of remunerative ore. The enumeration was not intended to be complete, but was apparently planned with a view to obtaining as large a number of representative facts as possible from which to draw general deductions.

[1] Tenth Census of the United States, Precious Metals, Vol. XIII, page 493.

As a census report the work was a failure, but as a scientific and technical report it has considerable value. The reasons for the failure of the 1880 census of the precious metals are concisely stated as follows: "After the work had been some time under way, it was found that both the time and the money which could be allotted to this branch were inadequate to carry it through with the perfection aimed at; that it was impossible to find the number of men required who were in every respect fitted for it by education and experience; and that among owners and superintendents of mines and reduction works, while with a very few unimportant exceptions the greatest willingness was shown to grant us all the information they possessed, it was often found that they were themselves unable to answer the questions we asked, either through want of system in keeping records, or because they had never thought of the importance or bearing of certain facts."[2] If the general canvass of all mines had been confined to the collection of a few main facts and the special technical features to representative mines, the work would have met with a larger measure of success.

The failure of the census of 1880 was apparently accepted as demonstrating the impracticability of including a large number of inquiries on technical and scientific subjects in a schedule to be used for a general canvass of all mines and quarries. The establishment in 1879 of the Geological Survey, and the collection by that office of technical and scientific information concerning the mineral resources of the country, obviated the necessity for the collection of such information by the Bureau of the Census. Therefore the scope of the census of 1890 was considerably curtailed, but followed in a general way the plan outlined in 1880.

Census of 1890.—The statistics for the mining census of 1890 are contained in a volume entitled "Mineral Industries." This report presents detailed statistics for each mineral, but no summary is given of the totals for all, though the following figures purporting to show the totals for the mining industry are obtained from the introduction to the report:

Employees	636,419
Wages paid	$265,290,643
Other expenditures	$115,874,135
Value of products	$587,230,662

The data given in the body of the report for each mineral are summarized in Table 4.

[2] Tenth Census of the United States, Precious Metals, Vol. XIII, page xi.

TABLE 4.—SUMMARY OF MINERAL INDUSTRIES: 1889.

MINERAL.	Number of mines, quarries and wells.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS.								Miscellaneous expenses.	Supplies and materials.	Value of product.
					Aggregate.		Above ground.			Below ground.					
			Number.	Salaries.	Number.	Wages.	Total.	Men.	Boys.	Total.	Men.	Boys.			
Total	59,494	$1,310,535,318	6,541	$5,520,600	536,043	$222,041,887	244,127	223,229	20,898	291,916	281,880	10,036	$39,521,596	$86,075,925	$438,111,548

[1] Includes salaries.
[2] Includes amount paid contractors.
[3] Statistics, except those of production, refer also to mines at which development work was done.
[4] Not separated into above and below ground.
[5] "Other expenditures."
[6] Including 9,969 "local mines," the product only of which is shown.
[7] Includes contract work.
[8] Stamp mills; number of mines or establishments otherwise not given. Statistics include those for stamp mills, concentrating plants, and copper refining.
[9] Value of product is that of copper refined.
[10] Firms; from textual statement, page 711: "The entire industry is controlled by three or four firms."
[11] Includes reduction works.
[12] Producers; from textual statement, page 700: "There were 24 producers who used steam power at their works."
[13] Includes smelting and refining.
[14] Smelting works.
[15] Value of product of zinc and lead mines, and, in some cases, value of ore treated by smelters and refiners; other statistics include smelting and refining.
[16] Not including value of manganiferous zinc ore, which was $54,560 at the mines.
[17] Organized companies.
[18] Springs.
[19] Producing wells.
[20] Includes value of pipe lines.
[21] Includes value of matte at mines, but not the value of other smelted nickel ores.
[22] Number of establishments given for South Carolina only.
[23] Number of openings.
[24] No production during the census year.

The totals for the United States, as shown by Table 4, are considerably less than the total referred to in the introduction to the report of the Eleventh Census. There is apparently no explanation of this difference, but it is believed that the figures given in Table 4 represent actual conditions as nearly as they can be ascertained from the data furnished at the Eleventh Census. Table 4 includes statistics for the following, which are not considered as forming a part of the mining census of 1902, i. e., aluminum, copper smelting, lead smelting and refining, and spelter and oxide of zinc, and mineral waters. Lack of uniformity is apparent in the statistics for the different minerals shown in Table 4. To illustrate: For aluminum and fibrous talc, marl, and ozocerite, product only is reported; for antimony, the number of establishments, capital, salaried employees, or salaries are not reported. The number of establishments and miscellaneous expenses are not reported for asbestos, while the production is given for California only, though the expenditures evidently include the nonproducing mines in Wyoming.

In addition to the mining statistics, the census of 1890 included statistics for the smelting and refining of gold, silver, copper, and lead and zinc. The statistics

apparently included all reduction works, though the general line of demarcation between manufacturing and mining agrees very closely with that followed in the canvass of the Twelfth Census. In the Report of Mineral Industries at the Eleventh Census it was stated that "the subjects taken for the investigation included all minerals which would have a definite market value, wherever they occur, provided the deposit contained the mineral in sufficiently pure form. This ruled out such minerals as ice, water (except mineral waters), sand for street paving, and other materials the condition of which is not changed, but which are simply made valuable by the work of placing in a special position, as earth for embankments."

"In the treatment of the various subjects the limit of the mining features was considered as reached when the product became a regular article of commerce."[1]

The following minerals were apparently produced in commercial quantities in 1889, though the report contains no data concerning them, i. e., borax, bauxite, cement, flint, feldspar, potters' clay, and rutile.

Census of 1902.—The scope of the census of mines in 1902, as stated in the act approved March 6, 1902, providing for a permanent Census Office, was intended to embrace the collection of statistics relating to "mines, mining, quarries, and minerals, and the production and value thereof, including gold in divisions of placer and vein, and silver mines, and the number of men employed, the average daily wage, average working time, and aggregate earnings in the various branches and aforesaid divisions of the mining and quarrying industries."

The purpose was to include in the enumeration the processes involved in the extraction from the earth of mineral products of all kinds. To accomplish this successfully the special agents engaged in the field-work were instructed to secure reports for all mines and quarries, and for reduction works connected with mines or engaged in reducing the ores containing the precious metals. It is believed that this census is as broad and as comprehensive in its scope as any of its predecessors; certainly it may be claimed that the canvass has been more complete than any statistical inquiry heretofore made concerning the mines and quarries of the United States.

No restrictions or limitations were established as to the size or importance of mines and quarries to be enumerated, except that the special agents were instructed to eliminate from the inquiry small placer gold mines at which less than two wage-earners were employed. The schedules received bear evidence that in many instances this instruction was not followed, and the reports included a number of small mines operated without hired labor.

Mineral springs were omitted from the canvass for the reason that in most cases the production is entirely spontaneous and does not require the employment of capital or labor except to place the product upon the market in the form of bottled mineral waters.

The production of salt was also omitted for the reason that a thorough canvass of the inquiry had been made in 1900 for the census of manufactures. The statistics are presented, with a report on the subject, in Part III of the Report on Manufactures.

What appears to be a serious defect in the published results of some of the earlier censuses is the absence of summaries showing the statistics other than those for quantity and value of product. Complete summaries by states and by industries for the United States, and for each industry by states and each state by industries were published at the census of 1870. At the census of 1880 a similar summarization was made for bituminous coal and lignite, anthracite coal, iron ore, copper ore, lead and zinc ore, and the minor minerals, but the absence of uniformity in the collection of statistics was referred to in the report of that census as follows: "It will therefore be seen that the duties of this office in regard to the statistics of mining were very different in different parts of the country, and further that the statistics were collected on blanks of different forms. The lack of uniformity in this respect added greatly to the difficulty of tabulation."[2]

The statistics for 1902 are presented in this report in summarized form and in detail. The tables show the statistics for the United States by states and by industries. Each industry is also presented by states and each state by industries. In connection with the reports on the different minerals, tables pertinent to the subject are presented.

A careful study of the statistics for the different censuses leads to the conclusion that there are no reliable comparative data for all mines and quarries other than the quantity and value of products.

The development of mining statistics may be considered as dating from the Tenth Census. The principal features of this development have been: (1) The separation of the statistics for mines and quarries from those for manufactures; (2) the adoption of special schedules designed to accentuate the peculiar features of the different minerals; (3) the employment of expert special agents to collect and present the data; (4) the collection of statistics in collaboration with the United States Geological Survey.

Mining and manufacturing.—Separate schedules were first provided for the mining industries at the census of 1880. Prior to that date the statistics had been collected in connection with the census of manufactures, the same schedule being applied indiscriminately to large manufacturing establishments, small shops, mines, quarries, and fisheries.

In some cases the mining industry is restricted to the digging of ore and the quarrying of rock—that is, to

[1] Eleventh Census of the United States, Mineral Industries, page ix.

[2] Eleventh Census of the United States, Mining Industries (excluding Precious Metals), Vol. XV, page xxii.

the minerals as delivered f. o. b. at the mine or quarry. In others a certain amount of labor is expended in the preparation of the product for the market. All labor expended on material after it is taken from the earth may be regarded as employed in manufacturing, and a strict demarcation between the two industries would so assign all such processes, but it is impossible in many instances to make this separation. To assist in the separation where possible and to aid in a more definite statistical presentation, all mines can be arranged in two groups: (1) Those where the product is marketed in the form in which it is extracted from the earth; (2) those where the initiatory manufacturing process is necessarily done at the mine or in immediate connection therewith.

No attempt was made to segregate the statistics for the two branches of industry, mining and manufacturing, respectively, prior to the census of 1870. At that census the distinction between mining and manufacturing was sharply defined, and the statistics for mining were presented in a separate series of tables. The reasons for the distinction were given as follows:

(1) Because these industries are in theory and in their practical relations essentially distinct. * * * The occupation of the miner is not so much unlike that of the artisan, yet writers on political economy have been quite generally disposed to hold that if the occupations of mining and fishing are to be assigned to any one of the three grand divisions of industry which have been indicated, it should be to agriculture, as dealing in the spontaneous products of the earth and the sea, and also as furnishing material in the earliest forms for subsequent processes of industry.

(2) For convenience of reference and citation. The statistics of mining * * * occupy so little space comparatively as not to be easily found upon occasion in voluminous tables of manufactures.

(3) Because the statistics of mining * * * with the present modes of collection are distressingly inadequate to the known facts of the case, and their addition to the tables of manufacturing industry amounts to a positive disparagement of the latter. The statistics of manufactures have their own faults, as is elsewhere frankly acknowledged, under the present census system of the United States, but they are incomparably more complete and accurate than any statistics of mining * * * to be obtained by existing machinery. To merge them with matter so defective is, in a degree, to subject them to the same discredit. A separation, therefore, is on all accounts desirable.[1]

The separation at the census of 1870 was effected in some cases by means of correspondence with the mine operators, so far as they were disposed to afford the information, and in other cases by estimates prepared according to approved formulas at the Bureau of the Census. The theoretical division between mining and manufactures thus applied is not wholly practical. Companies, firms, and individuals that operate both a mine and a reduction works, or that break, wash, screen, or roast the ore, almost invariably consider preparation for the market a part of the mining operations, and so report, insisting that the statistics can not be separated, since the employees were frequently engaged interchangeably on both branches of the work and no separate accounts were kept either of the wages or of other expenses.

At the census of 1880 the statistics related not only to mining, but included such technical data as to the various processes by which the metals are reduced from the ores as would serve to show the actual condition of the industry,[2] and therefore embraced manufacturing processes, such as the smelting of ores and the refining of petroleum. A more practical separation was attempted in 1890, but the statistics for that census also covered a number of manufacturing processes that are incident to the production of metal. At the census of 1902 the manipulation of the ore after it leaves the mine, if so interwoven with the business of mining as to be inseparable, has been considered a part of the mining industry. All other processes have been eliminated.

The combination of mining and manufacturing by the use of the same capital, the same wage-earners, etc., has been accentuated by the consolidation of industrial enterprises, carried to a high state of perfection during the past decade. If the statistics for mining and manufacturing were to be taken together it would be easy to find a common term for this union and comparatively simple to show the aggregate figures, but such work would not supply the demand for separate statistics for these important industries. Where the milling, separating, washing, burning, calcining, or other processes of reduction or manufacturing were carried out at the mine or quarry, the census of mines and quarries includes, as a rule, the employees, wages, miscellaneous expenses, and supplies and materials involved in the work of the entire establishment. At the census of 1902 the instructions to special agents on this subject were as follows:

There are several branches of mining in which the mineral products do not reach the market in the crude condition, but are subjected to certain processes at the mine or quarry before being regarded as marketable commodities. These may be processes of milling, separating, washing, burning, calcining, or other forms of manufacture. In some industries these processes are performed entirely at the mine or quarry, and in such cases the special agents are instructed that the census schedule should include the statistics of employees and wages, miscellaneous expenses, and supplies and materials involved in the entire work of mining the crude material and preparing the same for market. For example, the following branches of mining and quarrying are of this character: Emery and corundum mines, where finished emery wheels are frequently manufactured; mica mines, sheet and crushed mica being the finished product; graphite mines, where the crude graphite is refined; grindstone and millstone quarries, where grindstones and millstones are the finished products; mines or quarries of kaolin, flint, ocher, barytes, manganese, chalk, talc, mica, umber, sienna, and other iron-oxide colors, where the crude mineral is ground or otherwise prepared; marble, granite, and other stone quarries, where the stone is cut and dressed and monuments and tombstones are manufactured; slate quarries, where roofing slate, slate blackboards, school slates, and sanitary plumbing slate slabs are manufactured. In all such cases as the foregoing and others where any form of manufacturing is necessary at the mine or quarry before the product is placed on the market, the Census schedule should cover the entire work of the establishment.

[1] Ninth Census of the United States, Industry and Wealth, page 383.

[2] Tenth Census of the United States, Precious Metals, Vol. XIII, page x.

The practice followed and the line of demarcation adopted for the different minerals were as follows:

ABRASIVE MATERIALS:

Buhrstones and millstones: The quarries producing buhrstones and millstones almost invariably report the value of dressed stones, a segregation of actual quarrying operations from the finishing process being generally impracticable. The stones manufactured range in diameter from 14 to 84 inches, and are generally sold in pairs. A considerable by-product of paving blocks is included in the value of product reported by this industry.

Corundum and emery: These minerals are usually concentrated, cleaned, and pulverized at the mines, and the statistics are mainly those of the finished product.

Crystalline quartz: The value of the crude product is generally reported for this abrasive, although the crushing, drying, and screening operations incident to its preparation for use in the manufacture of sandpaper, garnet paper and cloth, etc., are in some instances carried on in connection with the quarrying. A segregation of quarrying and finishing operations is not always practicable, and of the total production reported, 20.9 per cent has been manufactured or finished to a certain extent after being taken from the quarry.

Garnet: Preliminary manipulation of the crude garnet ore is almost invariably carried on at the mines, and the cost of these finishing operations, consisting for the most part of the crushing of crystals to available sizes, washing, drying, and concentrating, is not separable from the expense of mining. The product reported for this abrasive may therefore be regarded as partly finished, and the value may be regarded as including somewhat more than that of the crude mineral.

Grindstones and pulpstones: A portion of the product of this abrasive is reported in the rough, that is, trimmed down for lathe finishing. The larger and more important establishments, however, complete the stone ready for mounting, in which instances the value reported is that of the finished product. Of the total production of grindstones, 71.9 per cent is a by-product of sandstone quarries. The capital and operating expenses for this part of the total production are therefore included in the statistics of the quarries in which the product was secured.

Infusorial earth, tripoli, and pumice: One-third of the product for this industry is reported by the Bureau of the Census as crude; this quantity represents about one-fourth of the total value. The remainder is finished at the mines by various processes. The process of working infusorial earth consists in burning and pressing into fire brick or drying, pulverizing, and bagging. The finishing of tripoli generally consists in burning, grinding, and washing, or, as is the case in the largest establishments of this kind, the product is manufactured by means of lathes, saws, and emery wheels into filter tubes, and disks, and shapes for water filters. The value reported for pumice is for the crude material. Its use, principally in the manufacture of certain kinds of soap, was by the company also controlling the mining operations; but the expense of this manufacture and the finished value of the product are not contained in this report.

Oilstones, whetstones, and scythestones: Of the total oilstone production in the United States 20.9 per cent is finished at the quarries, this amount representing 51.2 per cent of the total valuation. The finishing process, which consists in sawing or cutting the stone into strips averaging about 2 by 1½ by 8 inches and polishing these to a smooth surface, is necessary before the product is marketable. The crude value reported represents almost entirely the product of one company, owning quarries in various localities and shipping to one central plant for the finishing process. The United States Geological Survey reports the product of this company as it is finally manufactured, while the Bureau of the Census reports the production and value of the stone at the quarries.

Asbestos: Of the quantity shown for this mineral 59.9 per cent represents crude ore. The remainder was crushed, separated, and otherwise prepared at the mine for the market.

Asphaltum and bituminous rock: A large part of the asphaltum—elaterite, uintaite, etc.—was refined. Some of the bituminous rock was pulverized at the mine or quarry.

Barytes: The only preparation given this mineral at the mines was that of washing to free it, when necessary, from the associated earth or clay.

Bauxite: This mineral is usually sorted at the mine and subjected to solar or artificial heat to dry it prior to its shipment to market.

Borax: The product is that of refined borax, the crushing, grinding, mixing, crystallization, and other processes of refining being accomplished under the management of the mine owners.

Cement: In the case of cement the manufacture overshadows the mining of the raw material. Over 97 per cent of the Portland and natural-rock hydraulic cement production is made by establishments that mine, quarry, or excavate the raw material, and operate the mines or quarries and mills in conjunction. Only establishments excavating the whole or part of their raw material are included in the statistics. Although the reports do not permit of a complete segregation of the labor and expense for the mining and manufacturing processes, yet it would appear that in the case of the manufacture of natural rock cement the mining expense is not to exceed one-third of the cost of the marketable product, and in the case of Portland cement the portion on the side of mining or quarrying is very much less.

In the case of the cement companies using the marl deposits contiguous to the Great Lakes, which material is simply excavated with steam dredges, the cost of mining or excavation is an almost insignificant part of the cost of cement manufacture. Nearly 14 per cent of the Portland cement production was made from marl thus dredged or excavated.

Clay: Of the quantity of products shown, 17.3 per cent was prepared at the mine or quarry. This preparation consists principally of washing and grinding.

Coal, anthracite and bituminous: Anthracite coal is broken and screened and sometimes washed at the mine; bituminous is shipped as the run of the mine.

Copper ore: The reduction of the Lake Superior copper ores is done mechanically in stamp mills located at the mine, and the product, known as "copper mineral," is shipped to a smelter, operated either by the same or by some other company. As the stamp mill is in all cases regarded as part of the mine equipment, a thorough separation of the labor and expenses of the mine from those of the mill is impracticable; both have therefore been included in the mining census. The identity of the smelter, on the contrary, as distinct from the mine is maintained, as a rule, even in those cases in which it is owned and operated by the mining company. It has been possible, therefore, to eliminate smelters from the census of mines proper. The statistics for copper ores, other than those of the Lake Superior region, are generally for the crude ore; still in some cases the ore is dressed at the mines before smelting.

Flint and feldspar: The flint produced is properly quartz and not true flint, which is the nodular variety of silica occurring in calcareous strata, particularly in chalk. Approximately 52 per cent of the so-called "flint," or quartz, and feldspar production is marketed in its crude state and the balance as ground material. With the exception of the one process of grinding, the material is not subjected to manufacturing processes.

Fluorspar: Less than one-tenth of the quantity and about one-fifth of the value reported represents the product prepared at the mine for the market, the preparation consisting of washing, drying, and grinding.

Fuller's earth: The mining of fuller's earth is mere excavation and does not require skilled labor. The material is dried, ground, and in some cases sized, but is not otherwise subjected to manufacturing processes.

Gold and silver: The reduction or reworking of argentiferous and auriferous ores is carried on by establishments which, for the purpose of the mining census, are divided into four classes: (1) Reduction works, commonly known as "mills" (stamp and amalgamation, chlorination, cyaniding, and concentrating mills), which are located at the mine and operated by the mining company, the labor being employed interchangeably in the mining and the milling; (2) reduction works (mills) which are operated independently and in which the ore is either treated for a fixed compensation or purchased outright and the contents sold to smelters; (3) smelting establishments, which are usually operated independently, even when the mine and smelter are owned by the same company; (4) ore-dressing works (concentrators) which are operated by and in connection with the smelting establishments. The first two classes have been included in the mining census. The third class has been excluded, having appeared in the census of manufactures, 1900. The fourth class is so intimately allied with the smelting and refining of ores that it was impossible to make a separation, and therefore they have been classed also as manufactures.

Graphite: Almost the entire production reported is that of the mineral prepared for the market. The ore is crushed, stamped, separated, dried, and screened.

Gypsum: Nearly all of the gypsum quarried is calcined and manufactured into wall or cement plaster, and the manufacturing expense is the largest part of the cost of production of the marketable products. About 10 per cent of the gypsum quarried is reported as used in the crude state, and 7.4 per cent is ground for land plaster. The remaining 82.6 per cent is calcined into plaster of Paris, and most of the plaster of Paris is made into wall or cement plaster by the admixture of a retarder—fiber, hair, or other material.

Iron ore: Some of the ore is crushed, separated, calcined, and dried at the mines.

Lead and zinc ores: The dressing of these ores, preparatory to their final treatment by smelting, is usually done at the mine, either by hand jigs or in concentrating mills operated in connection with the mine; therefore no separation of labor and other expenses as between the mine and the mill is possible. There are a few custom mills which are not connected with any particular mine, but which either treat rough ores for a fixed compensation or purchase them outright and sell the dressed contents. Since the custom mills form but a small proportion of the total, all mills, whether connected with mining companies or independent, have been included in the mining census. Smelters, on the contrary, in those cases where they are owned by mining companies, as well as in all others, are operated as independent establishments, and they have not, therefore, been included in the mining census.

Lithium ore: This represents the crude ore, no manufacturing process being undertaken at the mine.

Magnesite: Of the quantity reported, 72.5 per cent was calcined at the mine, the remainder being the crude ore.

Manganese ore: The preparation usually given to the ore at the mine is crushing, washing, and screening.

Marl: The statistics presented in the report on marl pertain to the green sand marls of New Jersey and Virginia, which are used for fertilizing. One-third of the product is dried and ground, but with this exception the product is not subjected to any manufactur-

ing process. The mining of marl is simply a process of excavation.

Mica: The statistics include such manufacturing processes as are involved in the removal of adhering fragments of flint and feldspar and such parts of the mica itself as contain foreign ingredients. The sheet mica is prepared by splitting the blocks into sheets, which are cut to a size.

Mineral pigments, crude: Most of the processes necessary for the marketing of crude pigments are undertaken at the mine. The ore is disintegrated by exposure to the atmosphere, roughly crushed, dried, pulverized, and screened or separated. The ground ore is sometimes levigated and the settled products dried.

Monazite: Monazite is obtained in placer mining; nearly all of it for which statistics are given was prepared at the mine for the market by washing and sometimes by concentration. A little of the mineral was concentrated electro-magnetically.

Natural gas: The statistics are for the product as piped from the wells, and the value is that received for it at the point of consumption.

Petroleum: The statistics shown are wholly for the crude product.

Phosphate rock: Rock phosphate is usually washed to free it from sand and other impurities and kiln-dried to free it from moisture. When mined in too large bowlders to be easily handled, it is crushed. This is all done at or near the mine. River pebble is washed and screened immediately after being pumped up from the river bottom, and is dried with hot air and screened again before being marketed.

Precious stones: The value is reported for the product in the rough state as mined or found.

Quicksilver: Almost the whole of the output is that of the quicksilver extracted from its chief ore, cinnabar; only a small part of the ore was reported unconcentrated.

STEEL HARDENING METALS:

Chrome ore: The statistics are for the ore as mined, none of it having been prepared at the mine.

Molybdenum: The molybdenite was reported as crude, no process of manufacture being given.

Nickel and cobalt: The statistics are for the nickel and cobalt ore, washed and then smelted into matte at the mine.

Rutile: The report is for the crude mineral, in no way selected or concentrated.

Tungsten: Some of the ore is concentrated to from 60 to 65 per cent tungsten oxide, but much of it is the crude as mined.

Uranium and vanadium: The values are for the crude ores from which these metals are derived, except that a few tons of the uranium ore was reported as concentrated.

STONE:

Limestones and dolomites: Of the total product 18.3 per cent in value was for building purposes, 17.3 per cent for blast furnace flux, and the value of lime burned 30.7 per cent, most of the remainder being crushed for concrete, railroad ballast, roadmaking, macadam, etc., or prepared for curbing and flagging.

Marble: Of the total product, 45.1 per cent was sold rough. The remainder was sold dressed, for building purposes, for interior decoration, and for monumental, ornamental, and other purposes.

Sandstones and quartzites: Of these, 29.4 per cent in value was sold rough; 27.2 per cent was disposed of dressed for building purposes; and the remainder was crushed for concrete, ballast, riprap, etc., or prepared for curbing and flagging.

Silica sand: This, as shown here, is the product of quarries, not of sand banks, and was generally obtained from rock pulverized at the mine.

Siliceous crystalline rocks: Of the whole product, 24.3 per cent in value was sold in the rough state; 26.6 per cent was dressed for building purposes; 12.5 per cent was prepared for monumental work; and the remainder was crushed for roadmaking, riprap, etc., or prepared for curbing, paving, flagging, etc.

Slate: The slate is split and cut into roofing slate or made into slates and slate pencils, sanitary slabs, etc., at the mines, as it is necessary to work the material when moist. The proportion of the value of product prepared for roofing was 86.9 per cent.

Sulphur and pyrite: The statistics for the sulphur are for the refined; for the pyrite they are, generally speaking, for the substance as picked, rolled, jigged, and assorted at the mine. Some pyrite was a by-product of coal mines, being picked from the refuse.

Talc and soapstone: The talc is almost all ground for the market, and the soapstone is manufactured into washtubs, slabs, sanitary ware, etc., nearly all the product mined being manufactured by the original producers. The foliated variety of talc is usually ground into talcum powder and the fibrous variety into material for paper filling. All these processes are accomplished at or near the mine.

The limitation of the census inquiry to the operations at the mine or quarry has resulted in the exclusion of a considerable portion of the values generally assigned to the mineral products of the country. These differences are fully explained in the special reports for each mineral. A comparison of the quantity of the ores as reported to the Bureau of the Census for the year 1902, with the quantity of the metal obtained from the same class of ore during the same period, but possibly mined, at least in part, during the preceding year, illustrates the disparity in the quantities. It is possible to make

this comparison for a few minerals, and the totals are given in the following statement:

MINERAL.	Metal obtained, or manufactured product.	Product (quantity).
Iron ore, long tons		35,567,410
	Pig iron, long tons	17,821,307
Mineral pigments, crude, short tons.		35,479
	Mineral paints, short tons	[1] 60,491
Gold and silver ore, short tons		[2] 10,002,271
	Refined metal:	
	Gold, fine ounces	3,149,128
	Silver, fine ounces	42,746,064
	Copper, pounds	14,028,863
	Lead, short tons	205,519
	Zinc, short tons	35,789
Copper ore, short tons		11,780,064
	Refined metal:	
	Gold, fine ounces	92,911
	Silver, fine ounces	11,452,280
	Copper, pounds	625,004,529
	Lead, short tons	276
Lead and zinc ores, short tons		623,662
	Refined lead, short tons	[1] 79,445
	Spelter, short tons	[1] 156,927

[1] Reported by United States Geological Survey, zinc white and Venetian red omitted.
[2] Exclusive of placer bullion; this is shown in refined metal. Also exclusive of Alaska.

Special schedules.—At the census of 1840 the statistics for mines and quarries were collected on a schedule entitled "Schedule of mines, agriculture, commerce, manufactures, etc." The schedule used at the censuses of 1850, 1860, and 1870 was designated "Products of industry," and comprehended manufactures, mines, and fisheries. As already stated, the special schedules were introduced and carried to excess at the census of 1880, which was taken under the supervision of Gen. Francis A. Walker, who had already emphasized the necessity of such a schedule in presenting the statistics for the census of 1870. There were 44 special schedules, a separate schedule being provided not merely for each of the different minerals, except those tabulated as "minor minerals," but for the different conditions under which the same mineral was mined, and different sections of the country were assigned to different expert agents, and they in turn were permitted to use different forms of schedules for the same mineral as mined in their respective districts.

The use of special schedules was continued at the census of 1890, but the number of separate schedules was reduced to 23—1 general and 22 special. The special schedules were used to develop features peculiar to iron ore, gold and silver mines and reduction works, transportation of gold and silver ore and bullion, copper mines, lead mines, zinc mines, quicksilver mines and reduction works, manganese ore, precious stones, coal mines, distribution of coal for consumption, crude petroleum, natural gas, stone quarries, mineral waters, copper smelters and refiners, lead smelters and refiners, lead refiners, and zinc reduction works.

The object of the special schedule is to develop in detail the technique of an industry and to obtain from each establishment a schedule carefully filled out, the completion of which requires knowledge and time. The primary object of a census is to obtain complete and rapid enumeration, to show the magnitude of an industry, the number of people it employs, the amount paid in wages, and the quantity and value of its products. It is obvious, therefore, that these objects are in a measure antagonistic, and that the success of a census depends very largely upon the degree to which they can be harmonized. The schedules should not be so elaborate and technical that they can not be prepared by an agent of average intelligence, since they would so delay the canvass as to make a complete enumeration impossible.

The value of the statistics for a number of the minerals at the census of 1880 was seriously impaired by the adoption of a too elaborate and technical schedule.[1] The technical features of a special schedule are so interwoven with the general features to be developed by a census that it is, in many cases, impracticable to combine the two so as to obtain uniform statistics for all industries or all branches of the same industry. The use of special schedules is essential to the development of the census statistics for mines and quarries, but there are certain data—such as the number of different classes of employees, total wages, amount of miscellaneous expenses, cost of supplies and materials, and the quantity and value of the product—that should be called for uniformly in all such schedules. If these inquiries are not uniform it becomes impossible to make aggregates for all branches of industry. The omission of these general inquiries, and the lack of uniformity in the answers obtained in cases where they are included, are serious impediments to the use of the mining statistics of the censuses of 1880 and 1890.

The general tendency in statistical inquiries, as conducted by the Bureau of the Census, is to simplify the schedule.

An investigation designed to develop technical features can be conducted with better advantage and the results be more satisfactory if the inquiries are confined to representative establishments. Many of the inquiries concerning technical matters are not applicable to the major portion of the establishments enumerated, and therefore are confusing to the enumerator and to the person who furnishes the information.

The technical portions of the census of mines and quarries relate very largely to matters that are pertinent to the investigations of the United States Geological Survey, the results of which are given in the annual reports on the mineral resources of the United States. The collaboration between that office and the Bureau of the Census in the mining census of 1902 very largely relieved the Bureau of the Census from the task of obtaining technical data.[2] The special schedules of the Survey accompanied the more general Census schedule, both being prepared for every mine and quarry enumerated. There were 7 Census schedules, designated as follows:

Special schedule No. 6. All mines and quarries must be reported on this schedule except those for which special schedules are pro-

[1] Tenth Census, Mining Industries, Vol. XV, page xxiv.
[2] See pages 16 and 17 for memorandum concerning collaboration between the United States Geological Survey and the Bureau of the Census.

vided. Mines and quarries of the following minerals are to be reported on this schedule: Bluestone, granite, limestone, marble, sandstone, slate, trap rock, grindstones, millstones, soapstone and talc, cement rock, clay, barytes, emery and corundum, gypsum, mica, mineral paints, phosphate rock, iron ore, and manganese ore. Special attention is called to the fact that on this schedule also (special schedule No. 6) should be reported the nonargentiferous or soft lead mines located east of the Rocky mountains, the copper mines of the Lake Superior region, and zinc mines. Other minerals mined as such to be reported on this schedule, except where they accompany minerals of more importance, as platinum in gold placers, are the following: Antimony, asbestos, asphaltum, bauxite, borax, chrome ore, cobalt, feldspar, fibrous talc, flint, fluorspar, fuller's earth, garnet, graphite, infusorial earth and tripoli, magnesites, marls, molybdenum, monazite, oilstones, platinum, precious stones, pyrite, crystalline quartz, quicksilver, rutile, sulphur, tungsten, uranium, and vanadium.

Special schedule No. 8, for coal mines, both anthracite and bituminous, and anthracite coal washeries.

Special schedule No. 9, for petroleum and natural-gas wells.

Special schedule No. 10, for gold and silver and argentiferous and auriferous lead and copper mines.

Special schedule No. 11, for reduction works of the precious metals (other than smelters and refineries).

Special schedule No. 6a, a supplemental schedule for administrative and general offices. This schedule is intended for corporations, firms, or individuals operating more than one mine, quarry, or reduction works, with a central office for all of them. Upon this schedule should be reported the employees of such central office, with their salaries or wages, and all other employees whose work is not confined to one particular mine, quarry, or reduction works, such as general superintendents, machinists, surveyors, etc. All general expenses are also to be reported on this schedule and the data relating to capital stock, bonds, dividends, and assessments of incorporated companies. No data reported on this schedule should appear on the separate reports for the individual mines, quarries, or reduction works. Separate schedules are supplied for these individual plants.

Special schedule No. 6b, a supplemental schedule for bluestone, granite, limestone, marble, sandstone, slate, and trap rock quarries, upon which a full description of the quarrying and stone-dressing machines in use should be given. This schedule is to be filled out in addition to and supplementary to special schedule No. 6 for all stone quarries.

The special schedules of the Geological Survey were in the form of small cards and were provided for the following minerals:

Slate.
Marble.
Trap rock.
Granite.
Sandstone.
Bluestone.
Limestone.
Sulphuric acid.
Barytes.
Mineral paints.
Mica.
Salt.
Phosphate rock.
Gypsum.
Emery and corundum.
Millstones.
Grindstones.
Soapstone and talc.
Bituminous coal.
Anthracite coal.
Coke.
Coke, by-product plants.
Brick and tile.
Pottery.
Clay mined.
Mineral waters.
Cement.
Deep mines (precious metals).
Reduction works at mines.
Placer and surface mines (precious metals).
Local or custom mills or smelting works (precious metals).
Natural gas.
Crude petroleum.
Iron ore.
Manganese ore.
Gas, tar, and ammonia.
Precious stones.
Minor minerals (a general schedule for the production of all other minerals not included in the foregoing list).

The combination of the data contained on the Census and Geological Survey schedules makes possible the presentation of complete census statistics for the general features of the industries and also of technical information concerning each mineral. It is believed that this arrangement has resulted in the most complete and harmonious census of mines and quarries ever taken. It has made possible a separation of the purely scientific and technical inquiries from the statistical. At the same time, full information on each phase of the subject has been secured through the medium of the same agents.

Expert special agents.—At the censuses of 1850 to 1870, inclusive, the mining census was made by the United States marshals, and was incident to the enumeration of population and the collection of the statistics of agriculture and manufactures. The principal duty of the assistant marshals was the enumeration of population. The other three inquiries—agriculture, manufactures, and mining—were regarded as of much less importance, and it is probable that their importance was rated in the order named.

The first provision of law authorizing the employment of expert special agents is contained in section 18 of the act of March 3, 1879, providing for the census of 1880. This provision was reenacted in the laws providing for the Eleventh and Twelfth censuses and in the act of March 6, 1902, under which the census of that year was taken.

Persons engaged in an industry, or intimately associated with it through financial identification or through long experience in the compilation of statistical information concerning it, are in a position to select the data of greatest value and to pass upon the practicability of the schedule to be used in collecting these data. The principal advantage to statistical work from the employment of such persons is in the drafting of the schedules and analysis of the results. After the form of the schedule is determined and the inquiries thoroughly understood, the collection of the returns requires but slight, if any, technical knowledge. At the census of 1880 an attempt was made to employ experts to make the canvass,[1] but it was impossible to obtain a sufficient number of agents who had either a theoretical or practical knowledge of mining to do the work. At the census of 1890 experts and others were employed, the expert agents, as a rule, having supervision of the canvass for certain sections of the country or for certain minerals, irrespective of the location of the mines. In 1902 the schedules followed the general form used in collecting the statistics of manufacturing and mechanical industries. This was necessary in order that the totals for manufacturing and mining might be combined and the aggregate for all such industries presented. Moreover, as the technical schedules used by the Geological Survey were adopted by the Bureau of the Cen-

[1] Tenth Census, Precious Metals, Vol. XIII, page xi.

sus, there was no necessity for the employment of experts by the Bureau in the preparation of any of the returns. The canvass was made by the regular force of the Bureau, assisted by the office and field force of the Geological Survey.

Collaboration with the United States Geological Survey.—The United States Geological Survey was organized under the act of March 3, 1879, which established the office and, among other duties, provided that it should examine "the geological structure, mineral resources and products of the national domain." An act of Congress of August 7, 1882, provides that an amount not to exceed $10,000 may be annually applied by the Director of the Survey, under the direction of the Secretary of the Interior, to the procuring of statistics in relation to mines and mining other than gold and silver and to making chemical analyses of iron, coal, and oil. The first annual report of the Survey, which was transmitted to the Secretary of the Interior on November 1, 1880, covered the fiscal year ending June 30, 1880. Since then reports have been made annually, covering the calendar year.

In organizing the census of 1880, Gen. Francis A. Walker made arrangements with the Geological Survey to collect the statistics of mines and quarries.[1] Similar arrangements were made at the census of 1890.

The Geological Survey collects annually statistics of the quantity and value of production of the different minerals, in connection with its examination of the geological structure, mineral resources, and products of the national domain, and is necessarily in constant communication with mining companies, thus establishing an intimate relationship. Collaboration between the Survey and the Bureau of the Census in taking the decennial census of mines and quarries is, therefore, ideally correct, but the actual practice at earlier censuses of turning over to the employees of the Survey the entire work of collecting and compiling the census statistics resulted in a statistical presentation which was out of harmony with the presentation made in all other census industrial statistics. In other words, the mining census of 1880 was conducted on lines somewhat similar to those followed by the Survey in its annual reports, designed to show for the most part the quantity and value of the different minerals, their occurrence, an analysis of ores, and the possibility of development of the mineral resources of the country.

[1] In 1879 Prof. Ralph Pumpelly, head of the Division of Mines and Geology, United States Geological Survey, and the force working under him, were detailed to act as special agents of the Census Office to collect and discuss the statistics of the mining industries of the United States, exclusive of the precious metals. A report on the statistics and technology of the precious metals was prepared under the direction of Hon. Clarence King, Director of the Geological Survey, and the report on the production, technology, and uses of petroleum and its products was prepared by Mr. S. F. Peckham; on the manufacture of coke, by Mr. Joseph D. Weeks; and on building stones and the quarry industry, by Dr. George W. Hawes and others.

The report for the census of 1880 is contained in three volumes—one on the precious metals, another on nonmetalliferous minerals, and a third containing special reports on petroleum, coke, and building stones. Many of the reports are exhaustive, containing not only much statistical matter, but historical treatises and analyses as well. Uniform statistical aggregates, however, are wanting. The mining census of 1870 had proved to be so far from complete that in 1880 an effort was made to improve upon it by covering the entire field in an analytical and technical manner. Unfortunately, in doing this the necessity for a complete enumeration was lost sight of, and the inquiry was crushed by its own weight.

The United States Geological Survey had become thoroughly organized by 1890, and the mining census was taken under the direction of Dr. David T. Day, of the Survey, acting as a special agent of the Census Office. The method of presenting the statistics, however, was not in harmony with that adopted in making other census reports, and it is impossible to combine the totals of the different reports so as to show the aggregate for the mining, manufacturing, and mechanical industries of the country.

Although collaboration between different departments of the Government engaged in the same general class of work is likely to result in economy in administration, the act of Congress of March 6, 1902, provides that certain facts which differ radically from those compiled by the Survey are to be collated decennially by the Bureau of the Census. In order to compile these data and insure their harmony with other census reports, it is necessary that the Bureau of the Census have absolute control of both the canvass and the office work. Prior to the census of 1902, however, it was contended by the Survey that statistical conditions existed in the work of that office similar to those at the Bureau of the Census, and that if the statistics for the annual report on "Mineral Resources" were to be taken in collaboration with the census of mines and quarries, the fieldwork and the preliminary examination of the census schedules should be under the supervision of the Survey. It was therefore impossible to make arrangements that would be entirely satisfactory to both offices. The methods followed at the censuses of 1880 and 1890 having proved entirely inadequate, however, the following memorandum was agreed upon as the working basis of the two offices for the census of 1902:

Memorandum of agreement between the Director of the United States Geological Survey and the Director of the United States Census regarding the cooperation of the two offices in taking the mining census of 1902.

For the purpose of avoiding a duplicate canvass of the mining industry as provided for by the laws relating to the Geological Survey and the Census Office, of saving an unnecessary expenditure which would arise from such simultaneous duplication of the can-

vass, and to insure harmony between the statistics of the Geological Survey and of the Census Office, the following agreement has been reached:

I. The Geological Survey to take the general supervision of the fieldwork for the mining census, transmitting the several schedules of the Census Office to the producers in the same envelope with its own schedule and receiving them back in its own penalty envelopes; the Census schedules thus obtained by the Geological Survey to be transmitted to the Census Office as rapidly as received for examination and correction; such of the Census schedules as may require additional fieldwork to perfect them to be returned to the Geological Survey, at the discretion of the Census Office, in order that the desired corrections may be obtained. The clerical expense of handling the schedules and the correspondence connected therewith to be borne by the Geological Survey, but with the understanding that whenever more clerks are required than can be spared from the regular force of the Geological Survey the Census Office will detail such additional clerks from its regular force and will continue to carry them upon its pay rolls. All the work of tabulating and compiling the Census schedules to be done in the Census Office by the Census Office clerks. The Census Office to have the privilege of transcribing from the schedules of the Geological Survey such additional information contained therein as may be omitted from its own schedules for the purpose of greater simplicity.

II. The fieldwork which may be necessary in addition to correspondence in order to secure an early return for the mining census shall be done by the present force of trained experts—some 25 in number—employed by the Geological Survey in its regular fieldwork; and such additional clerks as may be required to complete the fieldwork with all possible rapidity shall be drawn from the regular clerical force of the Census Office.

III. The Geological Survey will contribute toward the expense of this fieldwork from its regular appropriation a sum equal to its annual expenditure for this purpose in previous years, the entire remainder of the cost of the fieldwork to be borne by the Census Office. This will involve, in many instances, a temporary transfer of the field agents of the Geological Survey from the rolls of that office to the rolls of the Census Office, this transfer to be made in every instance at the rates of compensation which they are receiving from the Geological Survey. The allowance for per diem expenses to be the same in every case as the Census allowance for its own field agents. The fieldwork for the mining census in 1890, as shown by the records of the Census Office, cost $142,113.47, being the amount paid to the maximum number of special agents employed, namely, 228.

IV. A representative of the Census Office to be detailed to act as assistant to the statistical division of the Geological Survey during the progress of the fieldwork. This is necessary in order that the Census Office may have a properly trained expert in its own clerical force thoroughly cognizant of all the details of the work, and thus qualified to oversee the tabulation and compilation of the Census statistics.

V. Whenever it may be so desired the Census Office to have the privilege of calling upon the experts of the Geological Survey to prepare the texts of its reports on the several branches of the mining industry.

VI. The schedules of the Census inquiry to be prepared and ready for delivery to the Geological Survey not later than January 1, 1903.

VII. The schedules to be thus handled by the Geological Survey to include all the mining schedules issued by the Census Office, including those for gold, silver, and stone quarrying.

The schedules of the Bureau of the Census and of the Geological Survey were mailed by the latter office to all mines and quarries known to be in existence, the letter of transmittal being signed by the directors of both offices.[1] The schedules were returned to the Survey and there given a cursory examination, the amounts reported in the schedules for the two offices being compared and the schedules separated. The schedules for the Census were then forwarded to the Bureau of the Census. This method, though it simplified the office work, multiplied the difficulties of the canvass. Each mine operator was required to prepare two schedules, a number of the questions on the two being similar. A large number of operators prepared the Survey schedule in conformity with their annual practice, but neglected the Census schedule. In a number of instances the Survey schedule required the quantity and value of the mineral marketed, while the Census schedule called for the quantity produced during the year. In other cases the Survey schedule required a report of the finished manufactured product, while the Census schedule called for the quantity and value of the crude ore.

It was often impossible to obtain a proper adjustment of these differences by correspondence, and in

[1] DEPARTMENT OF THE INTERIOR,
UNITED STATES GEOLOGICAL SURVEY,
Washington, D. C., December 31, 1902.

DEAR SIR: In accordance with an agreement between the Director of the Census and the Director of the United States Geological Survey, as shown in the subjoined letter, this Office will collect the data for the mining census in addition to the usual information collected annually for the report Mineral Resources. I therefore inclose herewith a copy of the census schedule, together with the card of this Office, with the request that you fill them both out and return them at the earliest possible moment. An addressed envelope, requiring no postage, is inclosed for reply.

Please answer every question in both schedules. All information furnished will be held strictly confidential. Only state, county, or district totals will be published. All Census employees are subject to a heavy fine for revealing information obtained for census purposes.

Your especial attention is called to the fact that the inquiry in regard to labor and wages is intended to include all the labor expended upon the product up to the time the material leaves the establishment, including grinding, washing, or other treatment.

Trusting that you will give this matter your prompt and careful attention, and thanking you in advance for your courtesy, I am,

Yours, very truly,

CHAS. D. WALCOTT, *Director.*

CENSUS OFFICE,
Washington, D. C., November 17, 1902.

Hon. CHARLES D. WALCOTT, *Director,*
United States Geological Survey, Washington, D. C.

SIR: In accordance with our understanding, you are hereby authorized to collect for the Census Office the schedules relating to the mines and mining industry required by section 7 of the act of Congress to create a permanent Census Office, approved March 6, 1902, at the same time and by the same methods employed in the collection of the annual mining statistics of the United States Geological Survey. This course will be in the interests of economy and efficiency, and will also save the producers the necessity of making out two schedules, at different times, which are in some respects duplicates of each other.

In transmitting the Census schedules to the producers and mine owners you are authorized to assure them that all information received on the Census schedules will be treated as strictly confidential and no publication will be made which will reveal the business or the operations of any individual, firm, or corporation in any branch of the mining or quarrying industry.

Very respectfully,

WILLIAM R. MERRIAM,
Director of the Census.

many cases the special agents found it difficult even by personal investigation to make a satisfactory explanation and to secure harmonious reports for the two offices. Many of these difficulties would have been obviated had the plan been tried of using a single schedule containing all of the inquiries needed for both offices. This, however, was believed to be impracticable, since considerable detail was required by the different reports.

The Census schedules contained inquiries concerning capital, employees, wages, daily rates of pay, materials, miscellaneous expenses, etc., as well as the quantity and value of the product. Under the conditions stated it would appear logical to have had the canvass made under the direct supervision of the Bureau of the Census, and to have included in the Census schedules the few additional inquiries as to finished product or products sold that are required for the annual report of the Survey. Such an arrangement would have required but one schedule for each producer.

III.

DIFFICULTIES AND DEFECTS OF THE ENUMERATION.

The claim is not made for the mining census of 1902 that a complete canvass has been possible, or that the figures presented are the result of an actual enumeration of all mines and quarries in operation during the period covered. The reports for the census of 1870 direct particular attention to the incompleteness of the statistics for 1860 and 1870. The reasons for the incompleteness of the statistics at the census of 1880, so far as they relate to precious metals, are given as follows:

1. From want of previous experience, the agents in charge could not distribute equally the ground to be covered among the experts employed, since the number of mines to be investigated bore no necessary relation to geographical area. As a consequence, toward the end of the time devoted to the investigation some regions received less attention than their relative importance merited.

2. The relative ability of the experts employed was necessarily unknown to the agents in charge until the investigation had proceeded so far that it was too late to make any radical change.

3. It was a practical impossibility to secure uniformity of ability and methods among so large a corps of experts as was necessary for the work. The result was that one would give more attention to one class of facts, another to another class, and, when totals were made up from the schedule returns, it was found that these facts were more complete in one region than another.

The lack of uniformity in the statistics for the different minerals has been referred to above under the title of "Development of mining statistics." It is impossible to determine the extent to which the production of minerals and ores by small operators was omitted from the reports for that census. Special attention appears to have been given to the small operators, and reports were secured from 9,969 small coal mines, classed as "Local mines and farmers' banks," in which coal was produced at irregular intervals. In referring to the incompleteness of the statistics for gold and silver in the report of the same census, it is stated that it was impossible to locate a vast number of independent miners producing gold in small quantities, often in remote and almost inaccessible spots; also that "while the average annual production of these prospectors or miners is small, the aggregate amount is considerable; but no full or accurate statistics of this portion of gold production can be obtained."

The census of 1902 does not contain reports from a number of the irregular producers and small mines. This is especially true of the small placer gold mines, irregular bituminous coal producers, and small lime and sandstone quarries. Schedules were mailed to every mine and quarry of which the name and address could be obtained, and in every case where a satisfactory schedule was not received by mail one was secured by a special agent. The special agents visited every section of the country and made diligent inquiry for mines and quarries not named on their official lists; every known source of information was exhausted in the preparation of these lists. It is believed, therefore, that the statistics are the results of as complete an enumeration as it is practicable to make. It is not contended that reports were secured from all mines and quarries, but that a large proportion of them have been reported is shown by the fact that returns were received for 5,345 operators of mines, quarries, and wells that reported an annual product valued at less than $500. In bituminous coal there were 798 producers of this class, and in limestone 1,296. For gold and silver, 3,252 reports were received for operators engaged in development work only, and 1,196 that reported a product valued at less than $1,000. The enumeration, however, did not extend to mining claims, although reports were received from 5,511 of such claims on which, in order to comply with the law and hold the claim, at least $100 worth of work was done during the year. The agents were instructed to omit from the enumeration the small placer gold mines at which less than two wage-earners were employed, unless such mines were in close proximity to other mines being enumerated. The value of the gold produced by the small placer miners and irregular operators is estimated at $1,633,835. This value is included as a separate item in the production for the United States, but there are no statistics concerning the number of people employed or the cost of materials and supplies.

In previous censuses all mines that did not report a production valued at $500 or more were usually omitted from the reports. This rule, if strictly followed, would exclude a large number of important properties, for some important mines are operated to only a limited extent, the major portion of the work being devoted to development. Therefore, no limit of this character was made at this census. It is admitted, nevertheless, that considerable quantities of mineral mined by farmers, ranchmen, contractors, and others were not accounted

for, because these men were not known as miners or quarrymen, and were overlooked by the agents. This kind of mining is carried on at irregular intervals, no record is kept of the production, and there are no available statistics concerning operations.

During the year 1902 the production of bituminous coal by irregular operators was greatly stimulated by the curtailment of the supply of anthracite coal. A large number of farmers worked their coal banks with farm labor whenever other duties would permit. Every means was exhausted to obtain the names and addresses of these producers, and a small schedule was sent to all whose names could be secured.[1] The report contains the statistics for 4,409 bituminous coal producers, and of this number 825 were reported on the small schedule as irregular operators. When the small schedule showed a production of 500 tons the regular schedule was sent and a full report as to employees, wages, etc., secured.

The nature of the work of the small, irregular operators precludes the possibility of a complete enumeration, nor is it essential for a mining census that returns be secured from all farmers and others who produced a few tons of mineral during the year, a large proportion of which was probably consumed in the local market. The reports for such small mines show, as a rule, only the quantity and value of the production. Most of the labor is done by the owner, and the expense for materials and supplies is so small that it is not reported.

In the mining of lead and zinc ore in Missouri, and in the mining of monazite, mica, and other minerals found in small quantities in different localities, it is the practice of the small producer to devote odd times to mining. In some cases the mining is done by a farmer on his own land; in other cases it is done on leased land or under a royalty agreement. In the majority of cases the ore is sold to one or more of the large establishments in the immediate vicinity, where it is reduced, refined, or prepared in some manner for the market. Under these conditions it is very difficult to obtain reports from the producers.

The census of zinc-lead mining in Missouri and Kansas presented peculiar difficulties, because of the method of the organization of this industry in that district. Only a few of the larger properties are operated by the owners. Nearly all of these properties are divided into tracts and leased to individuals or companies, who again divide them into small plots of an acre or less and sublease them to operators. In some cases this system of subleasing is carried still further. The actual operators are frequently practical miners, who work with pick and shovel. As the earnings of such operators are dependent upon the run of the ore, the mine is abandoned by the sublessee as soon as the returns prove unsatisfactory. A shaft is thus worked intermittently, a few weeks by one operator, then a few weeks by another, often changing hands several times during the year. The operators are constantly moving from one place to another. Those found on the properties by the Census agents in 1903 were only too often new operators, who had not been connected with the mines during the year 1902, for which information was sought, while those who had operated them in 1902 had moved away and could not be located. In such cases the only information available was that which could be furnished by the landowner. This information was naturally confined to the quantity and value of the product of the entire property; if the property was owned by a large company, its books, at best, might show the quantity and value of product of each of the first lessees. No further census data could be obtained.

The figures of production furnished by the owners, while correct in themselves, because taken from their books, presented still other difficulties, when treated in connection with other reports. A typical case could be described as follows: A report was secured from the owner covering the production of his entire property, with the exception, perhaps, of one tract leased to a large corporation, which furnished its own report. A few similar reports were received from first lessees of the owner, some of whom were active operators and some were sublessees. One or two of the sublessees could be located, and these furnished reports substantially accurate, although mostly from memory. Other first lessees could not be found or had transferred their leases to new holders, but some of their sublessees remained on the property and furnished reports to the census agent.

In order to avoid duplications, it was necessary to compare all these reports, and to subtract from the owner's report that which was reported by his first lessees and the sublessees. When it was attempted to balance the figures it appeared that the results could not be made to agree; for example, the sublessees showed a larger quantity of lead and zinc than that reported by the first lessee, while the value was considerably less than that reported by the owner. The explanation lay in the fact that part of the ore was sold in rough state by the sublessees to the owner, who concentrated it at his mill and disposed of it at a higher price. An inquiry addressed to one of the leading companies of the district brought the reply that the records of the company could not be adjusted to meet the figures furnished by the operators. The letter concluded by saying: "If it is your intention to reconcile their figures with those furnished from this office, we think you will have a hopeless and never ending task." Some of these discrepancies could be and were corrected at this office. If the value of zinc ore was reported by one operator at something like $3 per ton, whereas the average value reported by the owner and other operators on his property was about $30 per ton, it was safe to infer that the

[1] See Appendix A.

former represented rough ore and the latter dressed ore; if, on the contrary, the report showed that the lessee operated a concentrating mill in connection with his leased mine, the unusually low price of the ore would indicate a low percentage of zinc in the dressed ore. In the former case a substantial agreement between the conflicting figures could be attained by reducing the quantity of rough ore to terms of dressed ore, taking as a basis the average price per ton of dressed ore; in the latter case the quantity could not be disturbed. It is of course obvious that omissions and duplications could not be avoided. Still the census figures for the value of zinc and lead mined in the state of Missouri, which yields the bulk of the product, substantially agree with the returns secured, independently of the Bureau of the Census, by the state lead and zinc mines inspector.

The conditions prevailing in the region precluded anything like a complete and accurate presentation of all the labor employed in the mines. Aside from the numerous class of small operators who themselves work in the mines and are helped by members of their own family, or perhaps by one or two hired men, many of the operators who work the mines with none but hired labor frequently keep no books whatsoever. They may be able to state with substantial accuracy the number of men employed during the year and, by computation from the average rates paid by them, the amount expended for wages; but the items of "supplies" and "miscellaneous expenses" are in such cases nothing but rough estimates, and the accuracy of the results can not be vouched for. There is a large class of mines in which no miners are hired either by the day or by the ton, all mining labor being done on shares by "lessees," so called, who agree to pay the operator a stipulated royalty on all ore mined. In most cases of this class no records of the number of such lessees were kept by the operators, who could furnish no information beyond the total quantity and value of ore mined and the royalty received. Whenever practicable the number of men working on shares was secured from the landowner. The proceeds from the sale of the ore, less the royalty received by the landowner, represent the gross earnings of the miners, who are required to buy their own mine supplies. The number of such miners with their gross earnings, as far as reported, is shown separately, but is not included among regular wage-earners.

In the monazite industry the production is controlled by a single establishment, the product of a number of operators being purchased by one company, from which a complete report was secured. It was impossible to obtain reports from the small independent miners, but the number of such operators was known by the company and they were included as its employees. It was considered that the ore was mined on a contract basis, and the amount paid for it, or a proper proportion of such amount, was credited as wages.

The conditions under which mica is mined are somewhat similar to those prevailing in the monazite industry. Returns were secured from a number of the small independent producers, but a considerable proportion of the production could not be covered by such reports and was accounted for only in the schedules of the large establishments where it was prepared for the market.

There were only 17 regularly worked mines reported for the production of precious stones. Many of the precious stones were obtained by incidental discoveries or systematic search. The number of people engaged in this irregular work and the value of the stones are largely estimates based on information obtained from merchants and others familiar with local conditions.

In addition to the difficulties and the possibilities of error attending the collection of statistics of minerals for which the mining operations were similar to those enumerated above, there are uncertainties in connection with the collection of the reports and compiling the statistics for minerals mined by large and well organized companies. For instance, the schedule required the value of the product f. o. b. at the mine or quarry. A number of the anthracite coal companies contended that it was impossible to give such a value, or, in fact, any value for their product, since a portion was consumed at the mines in connection with their operation, considerable quantities were sold in the local market, and an unknown quantity was sold at a loss; also, that it was impracticable to deduct, or, in fact, to ascertain, the freight charges. The values are therefore largely estimated, based on the average value per ton of coal at the mine, the results being compared and checked with every available source of information. The production of petroleum is largely in the control of the Standard Oil Company, which contended that it was impossible to obtain separate reports from the individual producers. The company made one report covering the operations of 9,806 producers of oil in 39,301 oil wells in Pennsylvania, also similar combined reports for 2,123 producers and 8,443 wells in New York, 9,997 producers and 42,469 wells in Ohio, 4,435 producers and 12,951 wells in West Virginia. There were in all 7 schedules received from the company, which contained the statistics for 28,925 producers and 112,794 wells. In addition to the reports of the Standard Oil Company, there were 604 schedules received from 597 producers covering the operations of 5,877 wells. The 7 schedules from the Standard Oil Company covered 98 per cent of the producers and 95 per cent of the wells reported for the United States. Similar reports were made by the company for its production of natural gas, 4 schedules being received for 19 producers and 1,701 wells in Pennsylvania, New York, Ohio, and West Virginia, the producers forming 1 per cent and the wells 10.8 per cent of the total for the United States. Under these conditions it was impossible to localize the statistics for petroleum and natural gas by counties or to

check or verify the estimates of the number of employees, wages, expenses, etc. The schedules were carefully prepared and evidently cover the entire production of all the wells. The conditions under which the statistics have been compiled are in some respects similar to those prevailing in the mining of lead, zinc, mica, and monazite, in that the production is sold to one or more large establishments that put it on the market and thus in a measure control the output.

Since the recent discoveries of rich placer deposits have given prominence to the gold fields of Alaska, efforts have been made by the Government to obtain statistics by direct communication with the numerous owners of those mines. Mr. Charles G. Yale, special agent of the Bureau of the Mint, reported the following for the calendar year 1899:

> The population of these camps is more or less nomadic, moving from place to place as strikes in new creeks are announced. The season of mail communication among the camps along the Yukon river and creeks is very short, and when the spring "clean ups" have been made or the summer diggings begin to freeze the men come "outside" for the winter or go to larger camps. For these reasons it is almost impossible to obtain the desired statistical information as to the output of gold by correspondence with the individual miners.[1]

Dr. Cabell Whitehead, formerly assayer of the Mint, reported as follows from Nome, under date of September 5, 1900:

> Many men are prospecting throughout the entire country and we can only tell what they produce when they come in, as they are very secretive in all matters concerning their productions.[2]

The same was the experience of the agent of the Department of Labor, who investigated on the spot the conditions of Alaska gold mining. The difficulties in obtaining statistics of the placer mines in Alaska may be judged from the number of claims recorded, which in the Nome district alone had, up to January 10, 1900, reached 4,500.[3] This number is largely in excess of the total number of producing properties embraced in the present census of gold and silver mines for all states and territories. Important as it may be to ascertain the exact conditions under which an individual miner can nowadays produce gold without any capital, practically with his own hands, it was thought that this could be most successfully done in connection with the general census of population and occupations, whereas it could not be accomplished without an extraordinary expenditure of time and money as a part of the census confined to mines and mining. The quantity and value of the output of the Alaska gold mines are reproduced in this report from the report of the Director of the Mint, whose estimates are based upon the returns from the mints, assay offices, and from private refineries.

Porto Rico was the only insular possession in which the mineral resources were deemed of sufficient importance to attempt an enumeration. While it is known that a variety of minerals exist in the island, very few, if any, mines and quarries were operated as a regular business during the year 1902. The work was done at odd times and only sufficient material extracted to satisfy the local demand. It was difficult to locate the properties that had been worked, and practically impossible to obtain any information concerning the number of people employed or the quantity and value of the product. Under these conditions the statistics for the island are not comparable with those compiled for continental United States, and no reference is made to them in the general tables. The report on the mineral industries of Porto Rico consists principally of a compilation of historical data, a statement of the mining laws, and a list of the mineral deposits, with such information as could be obtained concerning the quantity and value of the products.

The omission of the small producers and the impossibility of obtaining individual reports from certain other producers, the data being included in a combined schedule, are the principal sources of error in the canvass. Another source of error is inherent in the preparation of the reports. A comparatively small proportion of the reports were prepared from data obtained from account books; but those which were prepared from such accounts were, as a rule, for the important operators and represented a large proportion of the production. The data in many of the schedules are estimates based on the recollection of the person answering the inquiries. This is particularly true of the answers to such inquiries as "The average number of wage-earners employed during each month" and "The average number of wage-earners at specified daily rates of pay." Few establishments keep books from which answers to inquiries of this character, covering a period of twelve months, could be readily obtained. If the information was obtained from the account books, it required an examination of a number of books and a large number of entries. The principal anthracite coal companies gave the office permission to examine their account books and compile the totals required for an answer to each inquiry. Two clerks were detailed to New York, N. Y., and Scranton, Pa., for this work. The method of keeping the pay rolls of the anthracite coal companies, from which was obtained the average number of persons employed by them during the year and the amount of wages paid, differs but slightly with the different companies. The original pay rolls are in sheet form, but by most companies are copied into books, these books being retained for office reference and the originals placed in vaults at the general offices of the companies or in storage. The census data were obtained from the office copies. The pay rolls are made out semimonthly. The names of the employees are written twice each month by some of the companies, while others arrange their books so that both the first and last halves of each month are carried on the same

[1] Report of the Director of the Mint upon the Production of the Precious Metals during the calendar year 1899, page 51.
[2] Ibid., 1900, page 56.
[3] Bulletin of the Department of Labor, 1900, "The Yukon and Nome Gold Regions," page 861.

set of sheets. The greater number of the companies keep their wage accounts "by collieries," having for each colliery a separate book in which are shown all the operations of that colliery during the year. Other companies keep these accounts "by months," having for each month a separate book in which are shown the operations of all their collieries for that one month. Usually the classes of employees were listed on the pay rolls in nearly the same order as they are shown in the census schedule, the list being headed by foremen, followed by clerks and the various classes as indicated; usually the employees above ground and those below ground are listed separately and designated as "outside" and "inside," respectively. Few, if any, of the companies distinguish on their pay rolls between boys under 16 years of age and employees over that age, and the records of none of the companies show the number of boys under 16 years of age in their employ. The average number of wage-earners employed during the year by these companies was obtained in all cases by first averaging each semimonthly sheet of the pay roll separately, adding together these sheet averages to obtain the average for the month, and finally dividing the sum of the monthly averages by 12 to show the average number employed during the year. The averaging of the number of wage-earners by sheets was accomplished by different methods. In some cases the number of men employed and the hours of labor were so uniform throughout the month that the number of names shown on the roll was used as the monthly average. As the rolls were usually headed by foremen, clerks, etc., the average numbers in these classes were easily obtained, and the deduction of these averages from the sheet average would show the average number of other employees; but in many cases where conditions were not uniform throughout the month, the sheet average was obtained by multiplying the number of employees on each sheet by the number of days in operation and dividing the product by the number of working days in the month, usually 25, 26, or 27 days. The sum of the sheet averages gave practically, but not exactly, the average for the month. To have obtained an exact average would have necessitated the addition of the total number of hours worked by each man during the month, the division of this aggregate by the number of hours fixed upon as constituting a day's labor, and the division of the quotient thus obtained by the number of working days in the month. From such monthly averages an exact yearly average could be obtained.

As no company keeps a record of the aggregate number of hours of labor performed each month, the length of time which would have been required to obtain the averages by this method would have caused too great a delay in the publication of the report. The two methods first mentioned gave sufficiently accurate averages for the months in which regular forces were employed throughout. It was found necessary, however, to adopt the latter method to obtain the average for those months during the strike when the number of employees was constantly varying.

While there were comparatively few operators for whom the preparation of the Census reports was attended with so many difficulties, still it is evident that the data furnished in reply to the majority of the inquiries were not obtained from the account books. It is probable that the percentage of error due to the fact that the answers are based on memory or rough memoranda, and not on actual records—a condition incident to all census work—is greater in the mining census than in any other branch of the industrial census.

IV.

OFFICE AND FIELD WORK.

The most important feature of the preliminary work of the mining census was the preparation of the schedules and instructions.[1] This work was started in November, 1902, and the last installment of the schedules was received from the Government Printing Office about the last of January, 1903. In the meantime the mailing of the schedules to the mine operators had been in progress and was completed shortly after the 1st of February, 1903. The mailing of the schedules and the general supervision of the fieldwork was under the direction of the Geological Survey. The theory of the work was that the schedules, instructions, and all circulars necessary for the canvass should be prepared at the Bureau of the Census and placed at the disposal of the Geological Survey for transmission to the field force. As the schedules were received, either by mail direct from the operators or from the special agents, they were immediately turned over to the Bureau of the Census for examination, all defective schedules being returned to the Survey for correction. The Survey schedule accompanied the Census schedule, and the quantity and value of the products reported on both were made to agree before they were separated. The Survey schedule was frequently filled and returned through the mail without the Census report, which was neglected until the field agent called. This neglect and the necessity for returning a large proportion of the Census schedules for correction resulted in the separation of the schedules in such a large number of cases that a general comparison of the final tabulations was necessary to insure an agreement between the two offices.

The schedules for bituminous coal, clay, stone, gypsum, cement, and fuller's earth were the only ones mailed directly to the mines from the Washington office of the Survey. All of the other schedules were sent in bulk to the offices of the field assistants of the Survey and mailed from there to the operators. About

[1] For copy of schedules see Appendix A, and for instructions see Appendix B.

three weeks were allowed for the return of the schedules by mail. The entire United States was then divided into districts, and the actual canvass was started on or about January 15, 1903, but at this time of the year some sections of the country are inaccessible, and it was impossible to employ the maximum field force until May, 1903, when there were 113 agents and clerks at work in the field or in the offices of the supervisory agents in different sections of the country. This number does not include the agents and clerks on the rolls of the Geological Survey who were engaged in collecting reports or other work incident to the canvass. The schedules were therefore returned by the mining company to the local office of the field assistant, given a preliminary examination there, then forwarded to the Geological Survey, where they were again examined before being sent to the Bureau of the Census. The final examination was made at the office of the Bureau, and letters criticising the schedules or calling for additional information were forwarded to the Geological Survey, and from there sent to the field assistant, who transmitted them to the mine operators by mail or through a personal visit of a field agent, or obtained the information personally, and again returned the schedules to the Geological Survey for transmittal to the Bureau. The practice of dividing the country into districts and placing the work in each district under the supervision of a local official is the most efficient way to conduct a canvass, but it is evident that these methods when followed in the mining census must lead to a duplication of work and more or less confusion, especially when schedules are being received not only from field agents who visit the mines, but also from the operators themselves.

The fieldwork of a mining census is necessarily based on lists giving the names and addresses of mines and quarries. The preparation of a complete list is therefore a very important part of the office work. The lists used for the census of 1902 were prepared in the division of mining and mineral resources of the United States Geological Survey, and are the outgrowth of the annual reports of that division on the mineral products of the country. The annual returns secured from the mines and quarries for these reports are of assistance in revising the lists at regular intervals. The names and location of new developments are obtained from technical journals and periodicals. All publications of this character are examined and notices of new mining enterprises are clipped. New producers are corresponded with to ascertain the full name, address, location of mine, and character of mineral. Confidential copies of the completed lists are sent at regular intervals to representative producers in different sections of the country for revision and the addition of new names. One of the principal advantages of the collaboration between the Geological Survey and the Bureau of the Census was the utilization of this list.

The special agents were instructed to supplement the official lists by careful inquiries in each locality visited, and to obtain reports from all mines that were in operation during any portion of the year. Two classes were excepted from these instructions; one was the small placer gold mine operators and the other the irregular bituminous coal miners. It is impossible to locate the small placer miners. Moreover, the only statistical information that could be obtained would be the quantity and value of their product, which can be estimated or secured from other sources equally reliable. Therefore no effort was made to secure reports from mines of this class unless the agent was in the vicinity in connection with other work and the preparation of the reports for the small mine would cause no delay. The reports for the irregular bituminous coal producers were obtained by correspondence.

Next to the schedule itself, the instructions for its uniform application are of the greatest importance. Such instructions were prepared and distributed to the special agents before they entered on duty. These instructions were of a general and special character; they defined the agents' duties and described the practices to be followed in securing schedules. They were used in connection with the instructions printed on each schedule, and were followed in the preparation of all reports.

The office work on the mining census was in progress from November, 1902, to July, 1904. During the greater part of this time comparatively few clerks were employed. The greatest number, 91, was reached on October 25, 1903, when the tabulation was at its height. The cost of the office work paid for by the Bureau of the Census was $77,853.17, and of the fieldwork $98,019.78, thus making the total cost of the mining census, exclusive of the final revision of the manuscript and printing and binding, $175,872.95. The schedules for the annual report of the Geological Survey were secured in connection with those for the Bureau of the Census, and the expenditure covers the collection of schedules for the reports of both offices. In some industries omitted from the mining census, but included in the annual reports of the Survey, such as the manufacture of gas, brick, pottery, etc., schedules were collected by the Census agents and turned over to the Survey. On the other hand, considerable Census work was done by the regular employees of the Geological Survey and at the expense of that office.

After the completion of the fieldwork several of the expert special agents employed by the United States Geological Survey in the preparation of the annual reports on Mineral Resources of the United States were retained by the Bureau of the Census to prepare the historical and descriptive text which accompanies the

statistics for the principal minerals. These special agents and the minerals assigned to each are as follows:

Dr. David T. Day	Platinum and iridium.
Dr. Joseph Struthers	Asphaltum and bituminous rock.
	Bauxite.
	Borax.
	Graphite.
	Magnesite.
	Mineral pigments, crude.
	Phosphate rock.
	Quicksilver.
	Sulphur and pyrite.
Dr. Joseph Hyde Pratt	Abrasive materials:
	Buhrstones and millstones.
	Crystalline quartz.
	Corundum and emery.
	Garnet.
	Grindstones and pulpstones.
	Infusorial earth, tripoli, and pumice.
	Oilstones, whetstones, and scythestones.
	Asbestos.
	Fluorspar.
	Lithium ore.
	Monazite.
	Talc and soapstone.
	Barytes.
	Mica.
	Steel hardening metals:
	Chrome ore.
	Nickel and cobalt.
	Molybdenum.
	Rutile.
	Tungsten.
	Uranium and vanadium.
Mr. George F. Kunz	Precious stones.
Mr. John Birkinbine	Iron ore.
	Manganese ore.
Mr. E. W. Parker	Coal, anthracite.
	Coal, bituminous.
Mr. Jefferson Middleton	Clay.
Mr. F. H. Oliphant	Petroleum and natural gas.

In addition to the above the text for certain minerals was prepared by experts, as follows:

Dr. George P. Merrill	Limestones and dolomites.
	Marble.
	Sandstones and quartzites.
	Silica sand.
	Siliceous crystalline rocks.
	Slate.
Dr. I. A. Hourwich	Gold and silver.
	Copper ore.
	Lead and zinc ore.
Mr. Story B. Ladd	Cement.
	Feldspar.
	Flint.
	Fuller's earth.
	Gypsum.
	Marl.

As previously explained, the schedules were mailed to all mines and quarries. There were received in all 38,151 schedules. Of this number 28,569 were for productive and 7,193 for unproductive and idle properties. In addition there were 2,389 schedules for mines and quarries that were abandoned, and therefore omitted from the tabulation. While comparatively few complete schedules were received through the mail for active properties, the mailing of the blanks was of great assistance to the fieldwork in disposing of the names of idle and abandoned mines and avoiding the necessity of visits by agents. The fieldwork was in progress from about January 15, 1903, to February 1, 1904. The total cost of the fieldwork, as paid for by the Bureau of the Census, was $98,019.78, which included $13,061.10 paid to supervising agents and their assistants who did no traveling. There were in all 122 different individuals, agents, and clerks engaged in the field, but of this number 39 were in a supervising capacity or employed in the offices of supervising agents and did no traveling. There were 83 persons engaged in the collection of schedules, the maximum number, 72, being at work in May, 1903.

As the special agents collected schedules from all mines and quarries in the localities visited, irrespective of the character of the mineral, the cost of the fieldwork for a specific mineral can not be computed with exactness, but the average cost per schedule for the active properties, both productive and unproductive, was about $3. Using this average, the following statement shows the approximate cost of the fieldwork for the principal minerals:

MINERAL.	Cost of fieldwork.
Total	$98,019.78
Bituminous coal	14,423.40
Anthracite coal	944.39
Iron	1,570.98
Gold and silver	47,815.13
Copper	509.67
Lead and zinc	2,974.04
Stone (all varieties)	16,842.78
All other minerals	12,939.39

V.

CLASSIFICATION OF MINERALS.

The statistics are presented in 52 classifications, each comprising the total for a distinct mineral or group of minerals. In some cases minerals or ores yielding two or more products were obtained from the same mine or quarry, and it was impracticable to separate the employees, wages, and expenses incident to the production of each. For instance, if the ore from a mine yielded both silver and copper, the latter being of the greater value, the report was assigned to copper, and all the employees, wages, and expenses were included in the totals for that mineral. If the chief product of a quarry was sandstone the report was classified as "sandstones and quartzites," though some of the product may have been manufactured into and sold as grindstones and pulpstones. In order to avoid duplication and, at the same time, show the total production for each classification, the by-products, when they formed the finished product of the mine or quarry, were added to the classification of which they formed a part. The following statement gives the quantity and value of the by-products that it was possible to segregate, the names of the classifications to which they were added, and the classification under which the

employees, wages, and expenses incident to their production are included:

BY-PRODUCT.	PRODUCTION.			Classification to which by-product should be added to obtain a total that is comparable with employees, wages, and expenses.
	Quantity.		Value.	
	Unit of measure.	Amount.		
Barytes	Short tons.	539	$1,618	Lead and zinc ore.
Buhrstones and millstones.	Stones	100	1,425	Siliceous crystalline rocks.
Cement			13,149	Limestones and dolomites.
Clay			400	Limestones and dolomites.
Feldspar	Short tons.	112	1,000	Flint.
Flint	Short tons.	1,254	2,593	Feldspar.
Grindstones and pulpstones.	Short tons.	35,503	403,066	Sandstones and quartzites.
Infusorial earth, tripoli, and pumice.	Short tons.	175	1,436	Talc and soapstone.
Lead and zinc ore	Pounds	1,625,813	37,212	Barytes.
Limestones and dolomites.			386	Coal, bituminous.
Limestones and dolomites.			124,687	Cement.
Limestones and dolomites.			5,100	Sandstones and quartzites.
Marble			8,433	Limestones and dolomites.
Mineral pigments, crude.			525	Slate.
Natural gas			103,112	Petroleum.
Oilstones, whetstones, and scythestones.	Short tons.	180	8,872	Sandstones and quartzites.
Oilstones, whetstones, and scythestones.	Short tons.	595	29,740	Grindstones and pulpstones.
Petroleum	Barrels	1,520	1,370	Natural gas.
Sandstones and quartzites.			1,273	Limestones and dolomites.
Sandstones and quartzites.			510	Grindstones and pulpstones.
Silica sand			50,811	Sandstones and quartzites.
Sulphur and pyrite	Long tons.	11,483	29,420	Coal, bituminous.

As shown by this statement, there are 18 of the classifications of minerals for which the values are increased by the inclusion of products obtained in connection with products included under other classifications. For instance, the total production of barytes amounted to 61,668 short tons, valued at $203,154. This includes 539 short tons, valued at $1,618, obtained as a by-product from lead and zinc mines. The employees, wages, and other expenses incident to the production of this by-product are included in the totals for lead and zinc ore. On the other hand, the production of lead and zinc was valued at $14,600,177, which includes 1,625,813 pounds, valued at $37,212, obtained as a by-product from the mining of barytes, the employees, wages, and expenses incident to the production of this by-product being included in the statistics for barytes. In other words, the products of certain mines were segregated so as to show the total production for a given mineral, irrespective of the class of mines from which it was obtained. This practice is in harmony with the methods of the United States Geological Survey, and the reason for its adoption was to obtain totals which would agree with the totals of that office. This method has been followed consistently in the statistics for all minerals except for argentiferous ores. Such a large percentage of silver, copper, lead, and zinc is obtained from the same ores that it was impracticable to segregate their values, and at the same time to present products which would be in any degree comparable for employees, wages, and expenses incident to their production. The totals for these minerals, therefore, present all of the statistics for the mines included in each classification. In treating the different ores, however, the production has been segregated so as to show the total for each metal.

While the theoretical accuracy of this method of tabulating the reports may be disputed, for the reason that it has resulted in assigning to some minerals a larger number of employees and a greater expense than are incident to their production, it is the only practicable way of presenting the data. It permits of a general summary for all minerals in each state and in the United States, and shows true conditions as to employees, wages, expenses, quantity, and value of the different products.

A similar method was followed in classifying the reports for some minerals in which a manufacturing process is carried on in connection with, and incident to, the mine or quarry. Instances of this character are, when limestone quarrying and cement manufacturing are done at a quarry and a part of the product of the quarry is sold in its crude state for building and other purposes, or when grindstones are made at a sandstone quarry and a portion of the quarried stone is sold for building or other purposes. Such quarries made only one report to the Bureau of the Census, and this was classified according to the product of chief value, the quantities and values of the different products being tabulated and presented separately in the reports on each mineral. For convenience in treatment the statistics for allied minerals or minerals used for similar purposes are grouped and discussed as a total and also individually. For instance, the report on "Abrasive materials" includes oilstones, whetstones, scythestones, grindstones, pulpstones, buhrstones, millstones, pumice, infusorial earth, tripoli, crystalline quartz, garnet, corundum, and emery.

A number of the substances usually included in reports on mineral products are the result of manufacturing processes, and therefore should not be included with statistics for mines and quarries. There are also a number of minerals that were not produced in commercial quantities in the United States during the year 1902, and therefore no statistics concerning them are given in this report.

The following summary shows the classification adopted for each mineral, the character of the substance included, and also the names and character of the substances omitted and the reasons for such omission.

ABRASIVE MATERIALS: This classification includes (1) abrasive materials that occur as rock formation and are cut and manufactured directly into the form desired, while retaining their original rock structure and appear-

ance, as oilstones and grindstones; (2) abrasive materials that occur as a constituent of either a rock or a vein and have to be mechanically separated from the associated minerals and cleaned, as corundum, emery, and garnet.

Buhrstones and millstones: Many varieties of stone are used in the manufacture of buhrstones and millstones, and these names are retained because the stones were formerly used for the same purposes as the regular buhr. The millstone varies from a sandstone to a quartz conglomerate. It occurs along the eastern slopes of the Appalachian mountains from New York to North Carolina and is known by different names. In New York the stone is called "Esopus stone;" in Pennsylvania it is known as "Turkey hill" and "Cocalico;" in Virginia, as "Brush mountain" stone, and in North Carolina the name in former years was "North Carolina grit."

Corundum and emery: This classification includes the varieties of corundum known as sapphire, which embraces all corundums of whatever color, that are transparent to semitransparent; also the translucent to opaque varieties of all colors, and emery, which is a mechanical admixture of corundum and magnetite or hematite. Of the total production shown for this classification a very small proportion was corundum proper, the production consisting almost entirely of the emery variety. The statistics do not include the manufacture of artificial corundum.

Crystalline quartz: Under this head is included the quartz that is used principally as a wood finisher and in the manufacture of sandpaper, scouring soaps, etc. The larger proportion of this quartz is used in the pottery and glass industry and is included with flint and feldspar.

Garnet: The statistics relate to the production consumed in the manufacture of garnet paper and emery wheels. The paper is used very extensively in the manufacture of boots and shoes. Garnet is found in many of the crystalline rocks, usually associated with mica in pegmatitic dikes.

Grindstones and pulpstones: The grindstone classification is composed almost entirely of the stones cut from the Lower Carboniferous sandstone beds of Ohio and West Virginia and the Lower Marshall series of Michigan. The Ohio and West Virginia sandstone is called the "Berea grit," because it has been so extensively quarried at Berea, in Cuyahoga county, Ohio. It is generally a fine grained and homogeneous variety. The color varies from a light drab to a light or steel blue. The pulpstones included are made from the Peninsula grit of Ohio, and are used for grinding wood pulp for the manufacture of paper.

Infusorial earth, tripoli, and pumice: Here are included all porous, siliceous earths of organic origin used in the manufacture of polishing powders and scouring soaps, water filters, fireproof building materials, etc. This classification includes also the solid pumice stone and volcanic ash which are used in the manufacture of various polishing powders and scouring stones.

Oilstones, whetstones, and scythestones: The term "oilstone" is applied to all stones used for sharpening tools to which oil is generally applied, but the same stone may be called an oilstone or a whetstone and, perhaps, a scythestone. The materials from which these stones are made are variable, but are of sedimentary origin, and include quartz-mica-schist, sandstone, novaculite, and the intermediate stones.

Aluminum: The metal is obtained by manufacturing processes, and the statistics are therefore excluded from this report. The production, which amounted to 7,300,000 pounds, is mentioned in the report on bauxite, which is the chief raw material used in its manufacture.

Antimony: This mineral is used chiefly for making alloys with lead, tin, zinc, and other metals. The supply is obtained from foreign and domestic antimony ores, hard lead, and regulus, or metal. There was no production of antimony metal from domestic ores during 1902, and therefore no statistics are presented. The quantity derived from other sources was estimated at 12,510,739 pounds.

Arsenic: Arsenious oxide (white arsenic) is obtained in the treatment of gold, silver, lead, or other arsenical ores, and being a separate manufacture is not shown in census mining statistics. The production of arsenic for 1902, as reported by the Geological Survey, was 1,353 short tons, valued at $81,180.

Asbestos: Two distinct minerals are mined and sold under this name. One is a variety of amphibole and the other is the fibrous variety of serpentine, known as chrysotile. The latter variety is the more valuable, but the production of the United States consists principally of the former. The statistics cover the production of both varieties. Asbestos is used in the manufacture of fireproof materials and wherever a nonconductor of heat is desired.

Asphaltum and bituminous rock: This classification includes the product obtained from the mining of the various kinds of hydrocarbon rocks that have an asphaltic base, and some of the purer forms of bitumen, as elaterite, gilsonite, and uintaite. The statistics do not include the asphaltum by-products of petroleum refineries, these being classed as manufactures, or the semifluid bitumen—maltha, or brea.

Ball clay: See Clay.

Barytes: What is known commercially as barytes is barite, a heavy, white mineral, used principally in the manufacture of paints and often called heavy spar, from its high specific gravity. A large proportion of this mineral is mined in an irregular manner by farmers and others who work at such times as their other employment will permit. The reports for all classes of operators are included.

Bauxite: The statistics for bauxite cover the entire production, which is consumed mainly in the manufacture of aluminum, although considerable is used for the manufacture of aluminum sulphate and crystallized alum.

Bismuth: There was no production of bismuth ore reported for 1902. The production in 1901 was reported as 318.6 short tons.

Bituminous rock: See Asphaltum and bituminous rock.

Bluestone: See Stone—Sandstones and quartzites.

Borax: The entire production of this most important salt of boric acid was obtained from the colemanite deposits in California and the marsh deposits of Nevada and Oregon. The statistics include the refining of the crude borax, which is closely allied with the mining.

Bromine: Bromine is one of the elements related in its chemical qualities to chlorine and iodine. It is a deep reddish brown liquid of a very disagreeable odor, emitting a brownish vapor at ordinary temperature. In combination it is found in minute quantities in sea water and many saline springs; occurs also in the mineral bromyrite. A large proportion of the product is obtained from deposits in Michigan. The processes are somewhat similar to those used in the production of salt. Both salt and bromine are classed as manufactures and excluded from this report.

Buhrstones: See Abrasive materials—Buhrstones and millstones.

Carbonate of soda: This product is the result of processes similar to those used in the manufacture of salt, being obtained by the solar or artificial evaporation of alkaline waters. It, as well as salt, was classed as a manufactured product at the census of 1900. The statistics, therefore, are omitted from this report. The entire production, 4,900 tons of refined soda ash, valued at $50,000, for the year 1902 was obtained from one establishment, the Inyo Development Company, of Inyo county, Cal., with general offices at Carson City, Nevada.

Carborundum: Is a product of manufactures, and, therefore, not included in this report. Its composition is, carbon, 32 per cent; silicon, 68 per cent. It comes from the furnace in the shape of black crystals, which are crushed, washed, dried, and sifted to uniform size. At the factory of the sole manufacturers, at Niagara Falls, the production in 1902 was 3,741,500 pounds.

Celestite: See Strontium ores.

Cement: The statistics relate only to the cement—Portland and natural rock—manufactured by establishments engaged in quarrying, but in addition to this product the total production of cement as reported to the Geological Survey is also mentioned. The marl excavated and used for cement is shown here, and not under Marl. The manufacture of pozzuolana, or cement from furnace slag, is not included.

Chromic iron ore: See Steel hardening metals—Chrome ore.

Clay: Includes kaolin, ball clay, fire clay, slip clay, stoneware clay, pipe clay, terra cotta, and other varieties of clay mined and sold as such. The statistics do not include the clay mined by operators who consume their output in the manufacture of brick, pottery, and other clay products.

Coal: Both the anthracite and the bituminous coal mines are included in this classification, the statistics being presented separately. Under bituminous is included semibituminous, lignite, and some coal locally known as anthracite. The anthracite is Pennsylvania anthracite, which is practically the whole production. The totals for bituminous coal include the output of the irregular, small producers.

Cobalt: See Steel hardening metals—Nickel and cobalt.

Coke: Coke is not shown, because a manufactured article and reported as such at the census of 1900.

Copper ore: The statistics of employees, wages, and expenses relate to the mines producing copper as a product of chief value; but the total quantity and value of the copper obtained from all ores, including the product of silver mines, is included, the amounts obtained from the different classes of ore being given separately. (See Gold and silver.)

Corundum: See Abrasive materials—Corundum and emery.

Crushed steel: This is a manufactured product and therefore not included in this report. It is used by granite and marble cutters; also in sawing, grinding, rubbing, and polishing stone, and by glass grinders. The sole producers manufactured 735,000 pounds in 1902.

Cryolite: There was no production of this mineral in the United States in 1902. It is a fluoride of sodium and aluminum, found almost exclusively in Greenland and sometimes called Greenland spar. It is used in the manufacture of aluminum and sodium salts.

Crystalline quartz: See Abrasive materials.

Dolomites: See Stone—Limestones and dolomites.

Emery: See Abrasive materials—Corundum and emery.

Feldspar: See Flint and feldspar.

Ferromanganese: This is an alloy of iron and manganese used in the manufacture of Bessemer steel. It is a manufactured article and therefore is not included in census mining statistics.

Fibrous talc: See Talc and soapstone.

Fire clay: See Clay.

Flint: See Flint and feldspar.

Flint and feldspar: This classification includes the flint or quartz mined as such, but does not include the crystalline quartz used for wood finishing or the manufacture of scouring soaps, which is shown under the class of Abrasive materials. Statistics are also shown for the entire production of feldspar, which is used largely in the pottery and porcelain industry and in the manufacture of scouring soaps and wood fillers.

Fluorspar: Fluorite of fluorspar is a calcium fluoride that is generally found in veins in limestones, sandstones, mica slate, clay, slate, and gneiss. The statistics cover the entire production, practically all of which is used as a fluxing material in steel works and blast furnaces.

Fuller's earth: The greatest part of this earth—a material resembling clay, but commonly lacking plasticity—is obtained in the vicinity of Quincy, Fla. The entire production is included. It is used in fulling wool and deodorizing and clarifying fats, oils, and greases. Refineries of lard, cottolene, and allied products are important consumers.

Garnet: See Abrasive materials.

Gold and silver: The statistics for gold and silver embrace both deep and placer mines and development work, and also the reduction mills and ore dressing works. In many instances gold and silver, and in some cases copper and lead, are obtained from the same ore. The statistics of employees, wages, and expenses for the precious metals are, therefore, presented in the same tables, but the production of each metal is shown separately. The value of the product is the value at the mine to the miner.

Granite: See Stone—Siliceous crystalline rocks.

Graphite: This mineral is sometimes called plumbago, black lead, or pot lead. It occurs as a form of carbon, and is the last form assumed in the natural change of vegetable matter into a mineral. The statistics include only the production and refining of the natural graphite, which is classed either as crystalline or amorphous.

Greensand marl: See Marl.

Grindstones: See Abrasive materials—Grindstones and pulpstones.

Grindstones and pulpstones: See Abrasive materials.

Gypsum: The statistics cover the crude gypsum—a calcium sulphate—marketed as such; also the product ground into land plaster and that calcined into plaster of Paris and wall or cement plaster.

Hübnerite: See Steel hardening metals—Tungsten.

Infusorial earth, tripoli, and pumice: See Abrasive materials.

Iridium: See Platinum and iridium.

Iron ore: The statistics include the different varieties of iron ore generally classed as (1) red hematite, including all anhydrous hematites, known by various names, such as red hematite, specular, micaceous, fossil, slate iron ore, martite, blue hematite, etc.; (2) brown hematite, including the varieties of hydrated sesquioxide of iron, recognized as limonite, gothite, turgite, bog ore, pipe ore, etc.; (3) magnetite, those ores in which iron occurs as magnetic oxide and including some martite, which is mined with the magnetite; (4) carbonate, those ores which contain a considerable amount of carbonic acid, such as spathic ore, blackband, siderite, clay, ironstone, etc. The statistics for manganiferous iron ores are also included. Argentiferous manganiferous iron ores are included in some cases with iron ores and in other cases with silver, according to the relative commercial value of the silver and iron contents.

Kaolin: See Clay.

Lead ore: See Lead and zinc ore.

Lead and zinc ore: Only nonauriferous and nonargentiferous lead and zinc ores are included. It is impracticable, in a majority of cases, to separate the statistics of employees, wages, and expenses incident to the production of each metal, and they are combined in the tables, but the quantity and value of each, and, in some cases, other statistics are shown separately. Totals for both lead and zinc include the dressing of the ore at the mine preparatory to its treatment at the smelter. The value is that of the contents at the mine to the miner. A considerable proportion of the lead product is obtained from silver ore, which carries with it also some gold. All the statistics relating to argentiferous lead ores, including the value of product, are given in the report for gold and silver mines, shown under Gold and silver.

Lepidolite: See Lithium ore.

Limestone: See Stone—Limestones and dolomites.

Limestones and dolomites: See Stone.

Litharge: This is a lead pigment, classed with white lead, red lead, etc., and being obtained by a process of manufacture is not included in statistics of mining.

Lithium ore: The two minerals thus far mined for their lithium contents are lepidolite and spodumene. Lepidolite is a lithia mica, in part a metasilicate of aluminum with potassium and lithium and varying amounts of fluorine and hydroxyl. Spodumene is a metasilicate of aluminum and lithium, generally containing a little sodium. It is not the metal lithium that is used in the arts, but its salts, principally lithium carbonate. This is used extensively in the preparation of mineral waters for medicinal purposes and in the manufacture of effervescing lithia tablets.

Lithographic stone: This is an even grained, compact limestone, usually of a drab or buff color, like that quarried at Solnhofen, Germany, and is used by lithographers. No production was reported for the year 1902. A report was received from a quarry in Kentucky that did only development work and prospecting. Lithographic stone has been found in Talladega county, Ala.; in Kern county, Cal.; in Illinois; at Anamosa, Jones county, and in Van Buren county, Iowa; near Elizabethtown, Hardin county, and in Clinton, Estill, Kenton, Rowan, and Wayne counties, Ky.; at Saverton, Ralls county, Mo.; in Clay and Overton counties, Tenn.; and in Llano county, Tex. The world's supply, however, has been obtained mostly from the quarries at Solnhofen, Bavaria. The imports for the year ending June 30, 1903, were valued at $131,015.

Magnesite: This is magnesium carbonate. The mining is confined to California. Only one producer re-

ported, and the statistics are grouped with All other minerals. The mineral is used especially in the manufacture of magnesite bricks for the refractory lining of furnaces and the manufacture of carbon-dioxide gas. When crude magnesite is decomposed by sulphuric acid there is a by-product of magnesium sulphate, or Epsom salts. Both crude and calcined magnesite are included in the statistics.

Manganese ore: The statistics for manganese ore include ores carrying over 44.3 per cent of metallic manganese. The manganiferous iron ores are treated under "Iron ores," and the manganiferous silver ores in some cases under "Silver" and in other cases under "Iron ores," according to the relative commercial value of the silver and iron contents. The chief use of manganese is in the manufacture of Bessemer steel.

Marble: See Stone.

Marl: Marl includes the green, blue, red, and yellow clayish earths used as fertilizers. The marl deposits extend from New Jersey to North Carolina, but the mines included in the statistics are in New Jersey and Virginia. In New Jersey the entire product is applied to the soil in the natural state, while in Virginia it is dried and ground for use in commercial fertilizers.

Mica: There are two varieties of commercial value—muscovite and phlogopite, but the former is more commonly found and mined. The value of mica depends on its occurrence in blocks or masses that are capable of being split into sheets a square inch or more in size, and the value of these sheets increases with their size, which varies from 1 inch square to 8 by 10 inches. Soap mica, ground to a flour, is used in the manufacture of wall papers, lubricants, fireproofing materials, novelties, etc. Sheet mica is used chiefly in stoves, for chimneys of incandescent lights, and for the insulation of electrical apparatus. The statistics embrace both sheet and scrap mica. A considerable proportion was mined by small, irregular operators, and the statistics for them are included in the total.

Millstones: See Abrasive materials—Buhrstones and millstones.

Mineral paints: See Mineral pigments, crude.

Mineral pigments, crude: Include the production of ores used in the manufacture of mineral paints. They consist of iron ores (red and brown hematites) that are ground and used in the manufacture of metallic paint, and are not included in the production of iron ores for the manufacture of iron; clay or other earths, including some mined as "Venetian red," containing iron used in making yellow, red, and brown pigments (such as ocher, umber, sienna, etc.); carbonate of zinc, slate (or shale) and soapstone, ground for pigment. No statistics of manufacture are given except such as are inseparable from the mining.

Mineral waters: The report on manufactures of the Twelfth Census and the annual reports of the Geological Survey contain statistics concerning the production and sale of mineral waters. These statistics have been omitted from the census of 1902 for the reason that mineral waters are not commercially classed as the product of a mine or quarry. They are produced under conditions that are entirely different from those prevailing in the mining industries. The employees engaged in the industry are devoted almost exclusively to the preparation of the product for the market, as there is practically no expense incident to the production of the water itself. The total production for 1902, as reported by the Geological Survey, was 64,859,451 gallons, valued at $8,793,761.

Molybdenum: See Steel hardening metals.

Monazite: This mineral is essentially an anhydrous phosphate of the rare earth metals cerium, lanthanum, and didymium. It is mined for its thoria contents, which are usually from 3 to 9 per cent, but have been found to vary from a fraction of 1 per cent to 32 per cent. The commercial deposits of monazite are found in placers of streams and rivers, also in old sand and gravel deposits of former streams, and are worked by sluicing the sands and gravels, principally by small, irregular operators, just as placer gold is washed. The thoria in the monazite and, in much smaller quantities, the lanthanum and didymium are used in the manufacture of the cylindrical hood or mantle of incandescent gaslights. The cerium oxalate obtained in the separation of the oxides is used in pharmacy.

Natural gas: The statistics relate exclusively to the production of natural gas, and the value of the product is the value at the point of consumption. The petroleum produced by gas companies and the statistics pertaining to it are included in those for petroleum.

Nickel: See Steel hardening metals—Nickel and cobalt.

Nickel and cobalt: See Steel hardening metals.

Nitrate of soda: No production of nitrate of soda was reported for the United States during the year 1902. A schedule was received from one California company owning a mine in Nevada, at which development work only was done. The world's supply is obtained principally from the natural beds of Chile. The total imports from all sources for 1902 were 661,348,800 pounds, valued at $5,996,205.

Novaculite: See Abrasive materials—Oilstones, whetstones, and scythestones.

Ocher: Ocher is a pigment used in the manufacture of mineral paints. See Mineral pigments, crude.

Oilstones: See Abrasive materials—Oilstones, whetstones, and scythestones.

Orange mineral: This is a lead oxide pigment largely used for paints. Being classed as a manufacture, it is not included in Census mining statistics.

Ozocerite: This mineral is also known as mineral wax. No production of the mineral, as such, was reported

for 1902. The entire product is obtained in the treatment of asphaltum, and therefore is classed for census purposes as a product of manufacture.

Petroleum: The statistics relate exclusively to the production of crude petroleum. Petroleum refining is classed as a manufacture, and the statistics are included in the census of manufactures of 1900. The production of natural gas by petroleum companies has been eliminated from the reports for such companies, and the statistics are included in the classification of natural gas.

Phosphate rock: This is a name given to various mineral deposits, consisting largely of calcium phosphates or iron and alumina phosphates, and used in the manufacture of commercial fertilizers. The statistics include the preparation of the rock for market when this is done at the quarry.

Pig iron: This is classed as a manufacture and was shown at the census of 1900. It is not included in mining statistics.

Pipe clay: See Clay.

Platinum: See Platinum and iridium.

Platinum and iridium: Almost the entire production of the rare metal platinum is obtained from placer gold mines. Iridium is closely associated with platinum and, not amalgamating, has not always been saved. Some platinum and iridium are also secured in the refining of gold. Platinum occurs generally in the native state. It is used chiefly in chemical manufacture and analysis and in electrical work. Iridium is used for the knife edges of balances and other hard wearing surfaces. There were no mines engaged in the production of platinum ore as a product of chief value; therefore it is impossible to show statistics of employees, wages, and expenses, such statistics being included in the report for gold. The production of platinum in 1902 from domestic mines, as reported by the United States Geological Survey, was 94 ounces, valued at $1,814, and of iridium, 20 ounces.

Pozzuolana or slag cement: This is a manufacture and is therefore not included in statistics of mining.

Precious stones: Under this heading are classed the following gems mined or found accidentally in this country in 1902: Sapphire, beryl, emerald, tourmaline, peridot, quartz, amethyst, agates, chrysoprase, silicified wood, opal, garnet, rhodolite, amazon stone, turquoise, chlorastrolite, mesolite, pyrite, anthracite, and catlinite. A considerable proportion of the product was the result of irregular work or incidental findings, and no employees, wages, or other expenses were reported for this portion.

Pulpstones: See Abrasive materials—Grindstones and pulpstones.

Pumice: See Abrasive materials—Infusorial earth, tripoli, and pumice.

Pyrite: See Sulphur and pyrite.

Quartzites: See Stone—Sandstones and quartzites.

Quicksilver: The production of this silver-white metal fluid is confined to California and Texas. The statistics include the production and the reduction of the cinnabar from which the quicksilver is principally obtained. The chief use of quicksilver, or mercury (its scientific name), is in the metallurgical treatment of gold and silver. It is also employed in the manufacture of vermilion, a pigment, in the manufacture of physical instruments, and as a medicine.

Red lead: Red lead is classed as a manufacture, and is not shown in mining statistics.

Rutile: See Steel hardening metals.

Salt: For census purposes salt is classed as a manufacture, and the statistics are included in the report on manufactures of the Twelfth Census. The total production for 1902, as reported by the Geological Survey, was 23,849,221 barrels, valued at $5,668,636. The chief salt producing states are Michigan and New York.

Sandstone: See Stone—Sandstones and quartzites.

Sandstones and quartzites: See Stone.

Scheelite: See Steel hardening metals—Tungsten.

Scythestones: See Abrasive materials—Oilstones, whetstones, and scythestones.

Sienna: Sienna is a pigment used in the manufacture of mineral paint. See Mineral pigments, crude.

Silica sand: See Stone.

Siliceous crystalline rocks: See Stone.

Silver: See Gold and silver.

Slate: See Stone.

Slate, ground for pigment: See Mineral pigments, crude.

Slip clay: See Clay.

Soapstone: See Talc and soapstone.

Spiegeleisen: This is an alloy of iron and manganese used in the manufacture of Bessemer steel, and, being a manufacture, is not included in census mining statistics.

Spodumene: See Lithium ore.

STEEL HARDENING METALS: The statistics for the several metals (except for manganese, which is shown separately) that are utilized largely, or in an experimental way, in the manufacture of steel or of steel products have been grouped under this classification. They are chromium, molybdenum, nickel, titanium, tungsten, uranium, and vanadium. Cobalt is included because it is associated with nickel in the matte. Except for nickel and cobalt, the value of which is the value of the matte at the mine, and tungsten ores, the value of which is their value more or less concentrated, the statistics are for the crude ores. Under this classification are shown chrome ore, molybdenum, nickel and cobalt, rutile, tungsten, and uranium and vanadium.

Chrome ore: This includes the statistics for chromite or chromic iron ore. Only one producer was reported. The ore is used in the manufacture of bricks for basic open-hearth furnaces, and from the metal a ferrochromium alloy is made which is em-

ployed in the manufacture of chromium steel. The chromium salts obtained are used in dyeing and in the manufacture of coloring pigments.

Molybdenum: The chief source of this metal is the mineral molybdenite, which is usually found foliated, massive or in scales, with a perfect basal cleavage and a metallic luster. Molybdenite generally occurs embedded in or disseminated through crystalline rocks, principally granite, gneiss, and granular limestone, and is found abundantly in the Western states. Besides being used in chemistry, molybdenum has in the last few years been found to give very beneficial properties to steel.

Nickel and cobalt: Most of the ores that contain one of these metals contain at least a small amount of the other, and in the smelting of the ores both the nickel and the cobalt go into the matte which is to be refined. The product is obtained principally from the smelting of lead ores at Mine La Motte, Mo. Nickel is used in the manufacture of tableware and for coinage and miscellaneous purposes, but its most important use is in the manufacture of a special steel from which armor plates, turrets, propeller shafts, etc., are made.

Rutile: Rutile is the only titanium mineral mined for commercial purposes. Considerable experimental work has been done with titanium in the manufacture of steel, but so far as known the metal has not yet been used in this way commercially. Iron has been made which contains a considerable proportion of titanium. Deposits are found in a number of states, but the beds in Virginia are the only ones that were productive in 1902. The principal use of rutile at present is as titanium oxide for coloring porcelain and in the manufacture of artificial teeth.

Tungsten: The sources of tungsten are scheelite, wolframite, and hübnerite. Of these, the one that can be used most advantageously in reducing it to the metal, or to the ferroalloy, is scheelite, a tungstate of calcium. Wolframite, which is the most abundant of the tungsten ores, is a tungstate of iron and manganese. Hübnerite is very similar to wolframite, and is essentially a manganese tungstate. The chief use of tungsten, either in the form of the alloy, as ferrotungsten, or as the powdered metal, is in the manufacture of tungsten steel.

Uranium and vanadium: The minerals that are the source of uranium are uraninite, gummite (an alteration product of uraninite), and carnotite. The last mineral contains also a considerable percentage of vanadium, a lead vanadate. Both uranium and vanadium are used in an experimental way in the manufacture of steel alloys, and increase the tensile strength and toughness of the steel. The metals are also in demand for their salts.

STONE: The statistics are shown under the following heads: Limestones and dolomites, marble, sandstones and quartzites, silica sand, siliceous crystalline rocks, and slate.

Limestones and dolomites: These include, besides the calcium carbonate (limestones), also stone containing calcium carbonate and magnesium carbonate in varying proportions (dolomites); also fossiliferous shell and coral limestones. The statistics include limestone used for iron flux and in the manufacture of lime.

Marble: Marble is limestone that by action of heat has been transformed to crystalline form. With marble is included some onyx marble, or travertine; also a small amount of serpentine or verd antique.

Sandstones and quartzites: This classification includes all consolidated sands. Among the varieties are the bluestone of New York and Pennsylvania, and calcareous sandstone; also the jasper of southern Minnesota, the lava of Douglas county, Colo.; ganister, a quartzite used as refractory material in furnaces, and some bituminous sandstone.

Silica sand: The crushing and grinding of the rock for the production of silica sand, used largely in the manufacture of glass, is in a number of cases done by sandstone quarries from which stone is sold for other purposes. But in cases where all, or practically all, of the product of the quarry was used for the manufacture of this sand it was treated as a quarry and the statistics are included under this classification. They do not include the digging of sand from sand banks, river beds, etc.

Siliceous crystalline rocks: This group of rocks includes granite, gneiss, mica schist, lava, andesite, syenite, quartz, porphyry, and trap. These are used for various purposes, such as building stone, foundation work, monumental stone, paving blocks, curbstone and flagstone, rubble and crushed stone for riprap, macadam roads, concrete, and railroad ballast. The kinds of stone treated under trap rock are trap, diabase, and diorite, which are quarried extensively in the New England states, and in New York, New Jersey, and Pennsylvania, and are used largely for paving stones and road metal; basalt, quarried in California for the same purposes; and gabbro.

Slate: Slate is quarried principally for roofing, but also for manufacture into slabs, slates, slate pencils, etc., the milling necessarily being done at the quarries while the stock is wet. Slate ground for pigment is included in Mineral pigments, crude.

Stoneware clay: See Clay.

Strontianite: See Strontium ores.

Strontium ores: The two minerals that are sources of strontium salts are celestite and strontianite. It is not the metal strontium that is used commercially, but its salts. Those that are most in demand are strontium oxide and strontium hydroxide, which are used in refining beet sugar and also in the defecation of sugar contained in molasses. Other uses are in the manufac-

ture of pyrotechnics, medicines, and chemicals. No production of strontium minerals has been reported since 1897, when 40 tons of celestite, out of 150 tons mined, was shipped from Put in Bay, Strontian Island, Ottawa county, Ohio.

Sulphur: See Sulphur and pyrite.

Sulphur and pyrite: The statistics for sulphur and pyrite, from which sulphuric acid is largely obtained, are grouped so as not to disclose the operations of a company engaged in the production of sulphur. By far the greater part of the sulphur is consumed in the manufacture of paper stock by the sulphite process.

There are two kinds of pyrite, iron pyrites and copper pyrites. Pyrite, which is mined principally for its sulphur contents, is commonly called iron pyrites, but that term includes marcasite as well as pyrrhotite. Practically all the ore is treated for the manufacture of sulphuric acid. The acid is used for medicinal and chemical purposes, and very largely in the refining of oils, manufacture of paper, fertilizers, etc. Some pyrite is mined as a by-product of coal, and this is included in the total.

Talc and soapstone: The statistics include a small production of serpentine and the production of pyrophyllite, both minerals being mined and used for the same purposes as talc. Three kinds of talc are included under this head: Foliated, from which talcum powders, tailors' pencils, etc., are made; fibrous, wholly mined in the state of New York and used in the manufacture of paper; and massive (which is steatite or soapstone), used for slabs, washtubs, sanitary work, etc. The manufacturing processes when conducted at the mines are included in the statistics.

Terra cotta: See Clay.

Tin: There was no production of tin ore in the United States during the year 1902. All the tin of commerce is obtained from the dioxide, which is called cassiterite by the mineralogist and tinstone by the miner. Some experimental or development work was done in the Black Hills region, and work was resumed on the deposits in the Santa Ana mountains in southern California. Tin is used principally in the manufacture of tin plate—sheet metal coated with tin. It also forms a part of several important alloys.

Trap rock: See Stone—Siliceous crystalline rocks.

Tripoli: See Abrasive materials—Infusorial earth, tripoli, and pumice.

Tungsten: See Steel hardening metals.

Umber: Umber is a pigment used in the manufacture of paints. See Mineral pigments, crude.

Uranium: See Steel hardening metals–Uranium and vanadium.

Uranium and vanadium: See Steel hardening metals.

Vanadium: See Steel hardening metals.

Venetian red: See Mineral pigments, crude.

Whetstones: See Abrasive materials–Oilstones, whetstones, and scythestones.

White lead: White lead is classed as a manufacture, and not shown in the census mining statistics.

Wolframite: See Steel hardening metals–Tungsten.

Zinc ore: See Lead and zinc ores.

Zinc white: This is a manufacture, and not included in the mining census.

There are many varieties of ores and metals included in the different groups or classifications. These ores and metals have been described with more or less detail in the reports for each classification, but in order to assist in the identification of the ore, the metal, and its chemical constituents, the following table, with the accompanying descriptive text relative to all ores of economic importance, is given:[1]

ORES OF ECONOMIC IMPORTANCE.

The accompanying table has been compiled from several authoritative sources,[2] the ores under each metal being arranged in the order of mineral species given in Dana's System of Mineralogy, sixth edition. The percentage compositions given in that work have been adopted and the metallic content has been calculated therefrom where necessary. In a mining region one often hears ores spoken of as running 90 per cent lead, 80 per cent zinc, and so on, when the purest crystallized minerals do not contain such amounts of the metals. The fourth column of this table shows the highest possible percentage of metal in the various ores, and the fifth column indicates the corresponding amounts of metal in the short ton (2,000 pounds) of pure ore. In a few instances the ore is of such variable or uncertain composition that the highest percentage of metal given by actual analysis has been quoted, instead of any theoretical amount. This has been indicated in the table by the use of brackets.

It must be remembered, however, that, with the exception of some ores of iron, tin, and quicksilver (mercury), the metalliferous ores as found in run of mine are not pure or unmixed minerals; on the contrary, they are in complex associations with one another. This is especially the case with silver ores (of which there are some thirty varieties, counting rare combinations), and, to a smaller degree, with ores of gold, nickel, antimony, zinc, and some other metals. Often it is the constituent of low ratio but high pecuniary value in these mixed ores that makes the mine worth working; or such a constituent may be the by-product of reduction which makes mining profitable. Furthermore, even with relatively pure ores, the accompanying gangue minerals—for instance, quartz, calcite, barite, and fluorite—seldom can be wholly removed by hand sorting or other means of concentration. These impurities and the unavoidable losses during the processes of reduction make the amount of metal actually won from an ore fall far below its theoretical chemical composition. The principal use of the table is to show the highest possible amount of metal that could be obtained from pure ores.

[2] Lehre von den Erzlagerstätten, by Richard Beck, Berlin, 1901; Ore Deposits of the United States and Canada, by James F. Kemp, fourth edition, New York and London, 1901; A System of Mineralogy, by Edward S. Dana, sixth edition, New York, 1895.

Percentage of metal contained in ores of economic importance.

CHEMICAL NATURE.	Kind of ore.	Chemical composition.	Per cent of metal.	Pounds of metal per short ton.	Remarks.
		Aluminum.			
Fluoride	Cryolite	Na_3AlF_6	12.8	256	Used also as a source of sodium and its compounds.
Oxide	Corundum	Al_2O_3	52.9	1,058	Used, however, mostly as an abrasive.
Oxide	Bauxite	$Al_2O_3.2\ H_2O$	39.1	782	Often furnishes more aluminum through presence of other oxides in the ore. Principal ore.
Silicate	Kaolinite	$2\ H_2O.Al_2O_3.2\ SiO_2$	20.9	418	
		Antimony.			
Sulphide	Stibnite (gray antimony, antimonite)	Sb_2S_3	71.4	1,428	Chief ore; often associated with galena.
Oxide	Valentinite (white antimony, senarmontite).	Sb_2O_3	83.3	1,666	
Oxide	Stibiconite (antimony ocher)	Sb_2O_3	74.5	1,490	Often furnishes more antimony through presence of other oxides. A by-product in lead smelting.
		Arsenic.			
Metallic	Native arsenic	As	100	2,000	Contains Sb, Ni, Fe, Mn as impurities. Rare.
Sulphide	Realgar	As_2S_2	70.1	1,402	
Sulphide	Orpiment (auripigment)	As_2S_3	61	1,220	
Arsenide	Löllingite	$FeAs_2$	72.8	1,456	Grades into leucopyrite, Fe_3As_4, with As 64.1 per cent.
Sulpharsenide	Arsenopyrite (mispickel)	FeAsS	46	920	Arsenic is obtained also from some nickel and cobalt ores, particularly smaltite and cobaltite.
		Bismuth.			
Metallic	Native bismuth	Bi	100	2,000	Rare.
Sulphide	Bismuthinite (bismuth glance)	Bi_2S_3	81.2	1,624	
Oxide	Bismite (bismuth ocher)	Bi_2O_3	89.6	1,792	
Carbonate	Bismutite (carbonate of bismuth)	$3\ BiCO_3 + H_6Bi_2O_6 + aq$	80.6	1,612	Composition variable.
Silicate	Eulytite	$Bi_4Si_3O_{12}$	75	1,500	Rare.
		Cadmium.			
Sulphide	Greenockite	CdS_2	77.7	1,554	The cadmium of commerce, however, is obtained from cadmiferous sphalerite (zinc blende).
		Chromium.			
Oxide (or chromate).	Chromite (chromic iron)	$FeCr_2O_4$	52.1 (Cr_2O_3 68.0)	1,042 (1,360)	Often has MgO and Fe_2O_3 replacing the FeO and Cr_2O_3.
		Cobalt.			
Sulphide	Linnaeite (cobalt pyrites)	Co_3S_4	57.9	1,158	Proportions variable. Co replaced usually to some extent by Ni, Fe, and Cu.
Arsenide	Smaltite	$CoAs_2$	28.2	564	Grades insensibly into chloanthite, $NiAs_2$.
Sulpharsenide	Cobaltite	CoAsS	35.5	710	
Arsenide	Skutterudite	$CoAs_3$	20.7	414	
Sulpharsenide	Glaucodot	(CoFe)AsS	23.8	476	Proportions variable.
Oxide	Asbolite (earthy cobalt)	Doubtful	Up to 32	640	
Arsenate	Erythrite (cobalt bloom)	$Co_3As_2O_8 + 8\ H_2O$	29.5	590	Cobalt is obtained also from arsenopyrite and chalcopyrite.
		Copper.			
Metallic	Native copper	Cu	100	2,000	Usually contains some silver.
Sulphide	Chalcocite (copper glance)	Cu_2S	79.8	1,596	
Sulphide	Covellite (indigo copper)	CuS	66.4	1,328	
Sulphide	Bornite (peacock ore)	Cu_3FeS_3	55.5	1,110	Often enriched by mechanical admixture of chalcocite.
Sulphide	Chalcopyrite (copper pyrites)	$CuFeS_2$	34.5	690	
Sulphantimonite	Bournonite	$(Pb, Cu_2)_2Sb_2S_6$	13	260	Contains 42.5 per cent lead and 24.7 per cent antimony.
Sulphantimonite	Tetrahedrite	$Cu_8Sb_2S_7$	52.1	1,042	Sb 24.8 per cent. Grades into tennantite, the sulpharsenite of Cu, containing Cu 57.5 per cent, As 17 per cent.
Sulpharsenite	Enargite	Cu_3AsS_4	48.3	966	As 19.1 per cent. Grades into famatinite, the sulphantimonite of Cu, containing Cu 43.3 per cent, Sb 27.4 per cent.
Chloride	Atacamite	$CuCl_2.3\ Cu(OH)_2$	64.5	1,290	Sometimes yields more copper, on account of admixtures.
Oxide	Cuprite (ruby copper)	Cu_2O	88.8	1,776	
Oxide	Tenorite (melaconite, black copper)	CuO	79.8	1,596	
Carbonate	Malachite (green carbonate of copper).	$CuCO_3.Cu(OH)_2$	57.4	1,148	
Carbonate	Azurite (blue carbonate of copper)	$2\ CuCO_3.Cu(OH)_2$	55.2	1,104	
Carbonate	Chrysocolla	$CuSiO_3 + 2\ H_2O$	36.1	722	Pyrite and pyrrhotite sometimes contain copper enough to pay for extraction.
		Gold.			
Metallic	Native gold	Au	100	2,000	Usually contains silver, up to 16 per cent. When more than 16 per cent silver is present the alloy is called electrum.
Telluride	Petzite	$(Ag, Au)_2Te$	25.5	510	Proportions variable. This percentage corresponds to ratio Ag : Au=3 : 1.
Telluride	Sylvanite	$(Au, Ag)Te_2$	24.5	490	Proportions variable. This percentage corresponds to ratio Au : Ag=1 : 1. Reported up to 29.35 Au.
Telluride	Krennerite	$(Ag, Au)Te_2$ (?)	34.8	696	Composition uncertain. Calaverite, another telluride, has yielded Au 40.92 per cent. Analyses have given from 5.8 per cent to 12.75 per cent Ag.
Sulpho-telluride	Nagyagite	$Au_2Pb_{14}Sb_3Te_7S_{17}$	7.46	149	Not common. Gold content calculated from average of recent analyses given by Dana. Gold is recovered also from pyrite, arsenopyrite, chalcopyrite, stibnite, and sphalerite (blende).
		Iridium.			
Metallic	Iridosmine	Ir Os	[40	800]	Variable.
Metallic	Platiniridium	Pt Ir			Variable.
		Iron.			
Oxide	Hematite (specular iron ore, red hematite).	Fe_2O_3	70	1,400	
Oxide	Martite (a variety of hematite)	Fe_2O_3	70	1,400	Replacing magnetite in Lake Superior region.
Oxide	Ilmenite (menaccanite)	$FeTiO_3$	47.3	946	Too refractory for use as a source of iron.
Oxide	Magnetite (magnetic iron ore)	Fe_3O_4	72.4	1,448	
Oxide	Franklinite	$(Fe, Zn, Mn)O.(Fe, Mn)_2O_3$	44.4	888	An important ore of zinc in northern New Jersey.
Oxide	Turgite	$2\ Fe_2O_3—H_2O$	66.2	1,324	Often confounded with hematite.
Oxide	Limonite (bog iron ore, brown hematite).	$2\ Fe_2O_3—3\ H_2O$	59.8	1,196	

Percentage of metal contained in ores of economic importance—Continued.

CHEMICAL NATURE.	Kind of ore.	Chemical composition.	Per cent of metal.	Pounds of metal per short ton.	Remarks.
	Iron—Continued.				
Oxide	Göthite	$Fe_2O_3—H_2O$	62.9	1,258	Often confounded with limonite.
Carbonate	Siderite (spathic iron ore)	$FeCO_3$	48.2	964	
Silicate	Chamosite	FeO, MgO, Al_2O_3, SiO_2, H_2O.	47	940	Uncertain composition. Iron declines to 33 per cent.
Sulphide	Pyrite (iron pyrites)	FeS_2	46.6	932	Contain 53.4 per cent sulphur and are used in the manufacture of sulphuric acid (oil of vitriol). Sometimes treated also for gold content.
Sulphide	Marcasite (iron pyrites, mundic)				Pyrites residue (=purple ore) is a commercial source of iron.
	Lead.				
Sulphide	Galena ("lead," lead glance)	PbS	86.6	1,732	Is also a very important source of silver.
Sulphantimonite	Jamesonite (feather ore)	$Pb_2Sb_2S_5$	50.8	1,016	Contains 29.5 per cent antimony.
Sulphantimonite	Bournonite	$(Pb, Cu_2)_3Sb_2S_6$	42.5	850	Copper, 13 per cent; antimony, 24.7 per cent.
Sulphantimonite	Boulangerite	$Pb_3Sb_2S_6$	58.9	1,178	Antimony, 22.8 per cent.
Carbonate	Cerussite (white lead ore)	$PbCO_3$	77.5	1,550	
Chloro-phosphate	Pyromorphite	$3Pb_3P_2O_8.PbCl_2$	76.3	1,526	
Chloro-arsenate	Mimetite	$3Pb_3As_2O_8.PbCl_2$	69.5	1,390	
Sulphate	Anglesite (lead vitriol)	$PbSO_4$	68.3	1,366	
	Manganese.				
Oxide	Franklinite	$(Fe, Zn, Mn)O.(FeMn)_2O_3$	[20.0	400]	Proportions very variable. Important ore of zinc in northern New Jersey; manganese not saved.
Oxide	Hausmannite	Mn_3O_4	72.5	1,450	
Oxide	Braunite	$3Mn_2O_3.MnSiO_3$	63.5	1,270	
Oxide	Polianite	MnO_2	63.1	1,262	
Oxide	Pyrolusite	MnO_2	63.1	1,262	Principal source.
Oxide	Manganite	$Mn_2O_3.H_2O$	62.4	1,248	
Manganate	Psilomelane	$H_4Mn_4O_5$ (?)	[58.6	1,172]	Proportions and composition variable.
Oxide	Wad	$MnO_2 + MnO + H_2O$	[69.2	1,384]	Proportions and composition variable.
Carbonate	Rhodochrosite	$MnCO_3$	47.8	956	
Silicate	Rhodonite	$MnSiO_3$	41.9	839	
	Mercury (quicksilver).				
Sulphide	Metacinnabarite	HgS	86.2	1,724	
Selenide	Tiemannite	HgSe	71.7	1,434	
Sulpho-selenide	Onofrite	Hg(S, Se)	83.8	1,676	Calculated for the ratio S:Se=6:1.
Sulphide	Cinnabar	HgS	86.2	1,724	Principal source.
	Molybdenum.				
Sulphide	Molybdenite	MoS_2	60.0	1,200	Nickel and cobalt are almost always associated.
	Nickel.				
Sulphide	Millerite	NiS	64.7	1,294	
Sulphide	Pentlandite	(Fe, Ni)S	22.0	440	
Arsenide	Niccolite	NiAs	43.9	878	
Sulphide	Linnaeite	$(Co, Ni)_3S_4$	28.9	578	Proportions variable. This amount calculated for ratio Co:Ni=1:1.
Arsenide	Chloanthite	$NiAs_2$	28.1	562	Grades insensibly into smaltite, $CoAs_2$.
Sulpharsenide	Gersdorffite	NiAsS	35.4	708	
Sulphantimonide	Ullmannite	NiSbS	27.8	556	
Carbonate	Zaratite	$NiCO_3.2Ni(OH)_2+4H_2O$	46.8	936	
Silicate	Genthite	$2NiO.2MgO.3SiO_2.6H_2O$	22.6	452	*Röttisite*, found in Voigtland, may be essentially the same as this.
Silicate	Garnierite	$H_2(Ni,Mg)SiO_4+aq$	[35.5	710]	Proportions very variable. This amount calculated from highest analysis given by Dana.
Arsenate	Annabergite (nickel ocher)	$Ni_3As_2O_8+8H_2O$	29.4	588	The most important nickel ore is pyrrhotite, a sulphide of iron (mostly Fe_7S_8), which sometimes contains more than 5 per cent Ni.
	Palladium.				
Metallic	Native palladium	Pd	100.0	2,000	Always alloyed with Pt, Ir, and other metals.
	Platinum.				
Metallic	Native platinum	Pt	100.0	2,000	Occurs, however, only alloyed with from 10 to 30 per cent Fe, Ir, Os, and other metals.
	Quicksilver. (See *Mercury.*)				
	Silver.				
Metallic	Native silver	Ag	100.0	2,000	Usually alloyed with gold; sometimes with copper.
Antimonide	Dyscrasite	Ag_3Sb	72.9	1,458	Other proportions cause the content of silver to range from 63.9 per cent to 94.1 per cent.
		Ag_6Sb	84.3	1,686	
Sulphide	Argentite	Ag_2S	87.1	1,742	
Telluride	Hessite	Ag_2Te	63.3	1,266	Often contains gold.
Telluride	Petzite	$(Ag,Au)_2Te$	42.0	840	Calculated for ratio, Ag:Au=3:1.
Sulphide	Stromeyerite	(Ag,Cu)$_2$S	53.1	1,062	
Telluride	Sylvanite	$(AuAg)Te_2$	13.4	268	Calculated for ratio, Ag:Au=1:1.
Sulphantimonite	Pyrargyrite (dark red silver ore)	Ag_3SbS_3	59.9	1,198	
Sulpharsenite	Proustite (light red silver ore)	Ag_3AsS_3	65.4	1,308	
Sulphantimonite	Stephanite (brittle silver ore)	Ag_5SbS_4	68.5	1,370	
Sulpharsenite	Polybasite	Ag_9SbS_6	75.6	1,512	Copper always replaces some of the silver.
Chloride	Cerargyrite (horn silver)	AgCl	75.3	1,506	
Chlorobromide	Embolite	Ag(Cl,Br)	65.1	1,302	Proportions of Cl to Br vary and change the total of silver present.
Bromide	Bromyrite	AgBr	57.4	1,148	
Iodide	Iodyrite	AgI	46.0	920	
					Much silver is obtained from galena, and it also occurs in tetrahedrite, sphalerite, pyrite, chalcopyrite, chalcocite, and other minerals in quantities of economic importance.

Percentage of metal contained in ores of economic importance—Continued.

CHEMICAL NATURE.	Kind of ore.	Chemical composition.	Per cent of metal.	Pounds of metal per short ton.	Remarks.
		Radium.			
.....	Uranite (pitchblende).....	U_3O_8	.....	.....	Radium, polonium, and actinium are extracted in minute quantities from these ores, especially pitchblende.
		$K_2O.U_2O.2U_2O_3.V_2O_5.3H_2O$ (?).			
		Thorium.			
.....	Monazite	$(Ce,La,Di)PO_4+ThSiO_6$(?)..	Tho_2, 6.49	130	Amount of thoria varies up to about 15 per cent; seems to occur as a silicate mechanically present in monazite.
		Tin.			
Sulphide	Stannite (tin pyrites)	$Cu_2S.FeS.SnS_2$	27.5	550	Proportions vary.
Oxide	Cassiterite (stream tin, wood tin)	SnO_2	78.6	1,572	Principal ore.
		Tungsten.			
Tungstate	Wolframite.....	$(Fe,Mn)WO_4$	60.6	1,212	Grades into hübnerite, $MnWO_4$, with 60.7 per cent tungsten.
Tungstate	Scheelite	$CaWO_4$	63.4	1,268	
		Uranium.			
Oxide	Uraninite (pitchblende)	U_3O_8	84.9	1,698	Chief ore; chief source also of radium, etc.
Oxide	Gummite.....	$U_2O_3.3H_2O$	72.7	1,454	
		Vanadium.			
Vanadate.....	Vanadinite.....	$3Pb_3V_2O_8 - PbCl_2$.....	10.9	218	
Vanadate.....	Mottramite.....	$(Pb,Cu)_3V_2O_8+2H_2(Pb,Cu)O_2$	10.5	210	
		Zinc.			Zinc minerals often are associated with lead ores.
Sulphide	Sphalerite (blende, black jack).....	ZnS.....	67.0	1,340	
Sulphide	Wurtzite.....	ZnS.....	67.0	1,340	
Oxide	Zincite	ZnO	80.3	1,606	
Oxide	Franklinite	$(FeZnMn)O.(Fe,Mn)_2O_3$....	[18.6	372]	Variable. Highest analysis recorded by Dana.
Carbonate.....	Smithsonite	$ZnCO_3$	52.0	1,040	
Carbonate.....	Hydrozincite.....	$ZnCO_3.2Zn(OH)_2$(?).....	60.5	1,210	Composition is uncertain and analyses vary.
Silicate.....	Willemite	Zn_2SiO_4.....	58.6	1,172	
Silicate.....	Calamine.....	$H_2Zn_2SiO_5$	54.2	1,084	

CHAPTER II.

SUMMARY AND ANALYSIS OF RESULTS.

I.

GENERAL REVIEW OF THE MINING INDUSTRY.

The statistics for the mining industries relate to the operations at mines, quarries, and petroleum and natural-gas wells, and embrace all minerals that were produced in commercial quantities during the calendar year ending December 31, 1902. These statistics are summarized in the following table:

TABLE 1.—SUMMARY: 1902.

	Total.	Coal.	Copper.	Gold and silver.	Iron ore.	Lead and zinc ore.	Petroleum and natural gas.	Stone.[1]	All other minerals.
Number of mines	151,516	5,986	144	2,992	525	559	134,477	5,764	1,069
Number of operators	46,858	4,528	144	2,992	332	557	31,489	5,470	1,346
Salaried officials, clerks, etc.:									
Number	38,128	17,427	1,208	3,480	2,405	910	4,956	5,279	2,463
Salaries	$39,020,552	$17,419,217	$1,768,456	$5,076,773	$2,113,230	$826,327	$4,797,105	$4,488,339	$2,531,105
Wage-earners:									
Average number	581,728	350,329	26,007	36,142	38,851	7,881	22,230	71,156	29,132
Wages	$369,959,960	$220,198,401	$21,151,405	$36,077,492	$21,531,792	$4,329,271	$16,178,640	$37,515,907	$12,977,052
Contract work	$20,677,938	$1,650,535	$188,768	$626,090	$425,292	$108,607	$17,415,632	$36,981	$226,033
Miscellaneous expenses	$71,771,713	$26,081,698	$1,397,465	$5,357,529	$8,257,714	$2,092,001	$21,723,983	$3,976,865	$2,884,458
Cost of supplies and materials	$123,814,967	$37,539,702	$11,083,175	$16,699,768	$9,005,608	$2,511,657	$24,388,767	$10,739,736	$11,846,554
Value of products	$796,826,417	$367,032,069	$51,178,036	$82,482,052	$65,465,321	$14,600,177	$102,265,602	$70,462,438	$43,340,722

[1] Includes limestones and dolomites, marble, sandstones and quartzites, silica sand, siliceous crystalline rocks, and slate.

The differences in the extent to which the manufacturing processes have been included in the statistics of prior censuses interfere with the comparability of the results, but in the following table the quantities and values reported for the Eleventh and Twelfth censuses have been reduced as nearly as possible to a comparable basis, and therefore the totals for copper, gold and silver, and lead and zinc for 1902 do not agree with the figures shown elsewhere in this report. The inclusion of the refined products for gold, silver, and other metals in this table has increased the value of products to $892,505,619, an excess of $95,679,202 over the $796,826,417 reported as the value of the products of the mines, quarries, and petroleum and natural-gas wells.

TABLE 2.—COMPARATIVE STATEMENT, QUANTITIES AND VALUES OF MINERALS: 1902 AND 1889.

MINERAL.	Unit of measure.	1902		1889	
		Quantity.	Value.	Quantity.	Value.
Total			[1] $892,505,619		$444,012,998
Antimony	Short tons	[2]	[2]	265	28,000
Asbestos	Short tons	2,505	46,200	30	1,800
Asphaltum and bituminous rock	Short tons	66,238	236,728	51,735	171,537
Barytes	Short tons	61,668	203,154	21,460	106,313
Bauxite	Long tons	29,222	128,206	[3] 21	97,335
Borax	Short tons	19,142	2,383,614	[4] 4,000	[4] 500,000
Buhrstones and millstones	Stones	6,667	59,808	[5]	35,155
Cement	Barrels	24,655,360	24,268,338	[4] 7,000,000	[4] 5,000,000
Clay	Short tons	1,455,357	2,061,072	[4] 329,665	[4] 635,578
Coal, anthracite	Long tons	36,940,710	76,173,586	40,714,721	65,879,514
Coal, bituminous	Short tons	260,216,844	290,858,483	95,629,026	94,346,809
Copper[6]	Pounds	639,033,392	71,192,014	231,246,214	26,907,809
Corundum and emery	Short tons	4,251	104,605	2,245	105,565
Crystalline quartz	Short tons	15,104	43,085	[5]	[5]
Feldspar	Short tons	45,287	250,424	[4] 7,806	[4] 39,370

[1] Exclusive of duplication of value of silver content of argentiferous iron ore, amounting to $883,987.
[2] No production from domestic ores.
[3] Aluminum, quantity reduced from 47,468 pounds.
[4] Not included as a part of the census; no statistics other than production reported.
[5] Not reported.
[6] Copper contents of all ores mined.

TABLE 2.—COMPARATIVE STATEMENT, QUANTITIES AND VALUES OF MINERALS: 1902 AND 1889—Continued.

MINERAL.	Unit of measure.	1902		1889	
		Quantity.	Value.	Quantity.	Value.
Flint	Short tons	36,365	144,209	[1] 12,447	[1] 49,137
Fluorspar	Short tons	48,818	275,682	9,500	45,835
Fuller's earth	Short tons	11,492	98,144	[2]	[2]
Garnet	Short tons	3,926	132,820	[2]	[2]
Gold, coining value[3]	Troy ounces	3,645,769	75,364,690	1,590,869	32,886,744
Graphite	Short tons	27,438	227,508	7,003	72,662
Grindstones and pulpstones	Short tons	55,657	667,431	[2]	439,587
Gypsum	Short tons	681,633	2,089,341	267,769	764,118
Infusorial earth, tripoli, and pumice	Short tons	6,415	55,994	3,466	23,372
Iron ore	Long tons	[4] 35,567,410	[4] 65,465,321	14,518,041	33,351,978
Lead[5]	Short tons	338,125	18,181,013	181,141	6,467,137
Limestones and dolomites			30,441,801		19,095,179
Lithium ore	Short tons	1,245	25,750	[2]	[2]
Lithographic stone	Short tons	[6]	[6]	18	243
Manganese ore	Long tons	16,477	177,911	24,197	240,559
Marble			5,044,182		3,488,170
Marl	Short tons	12,439	12,741	156,265	63,956
Mica:					
Sheet	Pounds	373,266	118,849	49,500	52,450
Scrap and waste	Short tons	1,400		196	
Mineral pigments, crude	Short tons	35,479	360,885	[7] 38,184	[7] 483,766
Monazite	Pounds	802,000	64,160	[2]	[2]
Natural gas			20,867,863		21,097,099
Oilstones, whetstones, and scythestones	Short tons	3,876	113,968	2,991	32,980
Ozocerite, refined	Pounds	[2]	[2]	50,000	2,500
Petroleum	Barrels	89,275,302	71,397,739	35,163,513	26,963,340
Phosphate rock	Long tons	1,548,720	4,922,943	550,245	2,937,776
Platinum and iridium	Troy ounces	[8] 94	[8] 1,814	500	2,000
Precious stones			328,450		188,807
Quicksilver:					
Crude	Short tons	11,727	1,550,090	2,750	[2]
Refined	Flasks	34,291		26,484	1,190,500
Sandstones and quartzites			10,601,171		12,066,076
Silica sand	Short tons	445,903	421,289	[2]	[2]
Siliceous crystalline rocks			18,257,944		14,464,095
Silver, coining value[9]	Troy ounces	[4] 55,911,946	[4] 71,077,562	51,354,851	66,396,988
Slate			5,696,051		3,482,513
Sulphur and pyrite	Short tons	232,819	947,089	106,100	209,969
Talc and soapstone	Short tons	97,563	1,138,167	36,461	475,878
Tungsten	Short tons	184	5,975	[2]	[2]
Uranium and vanadium	Short tons	3,810	48,125	[2]	[2]
Zinc ore[10]	Short tons	527,121	9,006,361	234,503	3,049,799
All other minerals[11]	Short tons	3,536	49,256	3,151	73,000

[1] Not included as a part of the census; no statistics other than production reported.
[2] Not reported.
[3] Fine gold contents of auriferous ores and placer bullion.
[4] Silver content of argentiferous iron ore—1,621,602 troy ounces valued at $883,987, included in both iron ore and silver.
[5] Nonargentiferous lead ore and lead contents of argentiferous and copper ores.
[6] No production.
[7] Includes slate ground as a pigment, 2,000 long tons, value $20,000.
[8] Platinum only; entire production obtained in placer mining and the refining of auriferous ores.
[9] Fine silver contents of argentiferous ores and placer bullion.
[10] Zinc ore and zinc contents of auriferous and argentiferous ores.
[11] Includes chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile for 1902, and chrome ore, nickel and cobalt, and rutile for 1889.

The reports for each census, beginning with 1850, have included statistics for mines and quarries, but prior to the census of 1870 these statistics are so interwoven with those for manufactures that it is impossible to make a satisfactory segregation. At the censuses of 1870 and 1880 the canvass for the collection of mining statistics was so defective that the results can not be used for general comparisons to show the increase in all branches of mining. A complete canvass was made at the Eleventh Census, which covered the year 1889, but the results were not summarized nor were the data, except for the quantity and value of products, compiled on uniform lines.

The only information concerning the employees, wages, and other expenses for all branches of mining published at the Eleventh Census is contained in the following statement taken from the text of the report: "In all, 636,419 persons found employment directly in the mining industry, and depended upon this industry as their regular means of support. They received in wages $265,290,643, or more than 52 per cent of the entire value of what they produced. In addition, the other expenditures aggregated $115,874,135."[1] In 1902 there were 38,128 salaried officials, clerks, etc., with salaries amounting to $39,020,552. The average number of wage-earners employed during the entire year was 581,728, and they received in wages $369,959,960. The miscellaneous expenses and cost of supplies and materials amounted to $195,586,680, and the products were valued at $796,826,417. The products reported for 1889 amounted to $587,230,662,[1] but they include salt, pig iron, and other substances omitted from the mining census of 1902. Reducing the production to a comparative basis, as shown in Table 1, by including for 1902 the value of refined copper, the coining value of gold and silver, and the lead and zinc contents of argentiferous ores, and eliminating from 1889 the products not included in the

[1] Eleventh Census. Report on Mineral Industries, page xi.

mining census of 1902, the total for 1889 becomes $444,012,998, as compared with $892,505,619 for 1902, an increase of $448,492,621, or 101 per cent. The number of persons who found employment directly in the mining industries at the Eleventh Census was evidently reported on a different basis from that used at this census. The average number shown for 1889 was the average number employed during the time the mine was in operation, while the average number shown for 1902 is the average number for the whole year, whether the mine was in operation all the year round or a part of the time only. The value of products reported for the census of 1902 is the amount received by the mine operators, and should not be confused with the value of the finished mineral product or the refined metallic contents of the ore, such as iron, antimony, and nickel. The quantity and value of the refined metallic contents and the coining value of some ores, such as gold and silver, are given for 1902 in Table 1 in order to obtain comparable totals. The separate quantity and value of gold, silver, copper, lead, or zinc, when, as frequently happens, two or more of them are obtained from the same ore, can not be definitely determined until the ore has been smelted. Smelting is a manufacturing process, and is therefore omitted from the mining census, but the metallic contents of the ore and bullion produced in continental United States during the year 1902 and the gross value of the same, as computed from the reports to the Bureau of the Census, were as follows: Gold, 3,242,039 ounces, valued at $65,628,906; silver, 55,819,946 ounces, valued at $28,166,094; copper, 639,033,392 pounds, valued at $71,192,014; lead, 338,125 short tons, valued at $18,181,013; zinc, 527,121 short tons, valued at $9,006,361. These values are the values at the mines. Gold and silver were reported at the Eleventh Census in troy ounces and coining value. Computed on the same basis, the production of continental United States for 1902 amounted to 3,242,039 ounces of gold, valued at $67,018,890, and 55,819,946 ounces of silver, valued at $72,171,227. No canvass of the gold mines of Alaska having been made by the Bureau of the Census, the estimate for Alaska made by the Director of the Mint is accepted by this office. The total production of the United States for 1902 is accordingly estimated as follows: Gold, 3,645,769 ounces, valued at $75,364,690; silver, 55,911,946 ounces, valued at $72,290,176. The Director of the Mint reports the production of gold for the United States for the calendar year 1902 as 3,870,000 ounces, valued at $80,000,000, and the production of silver as 55,500,000 ounces, valued at $71,757,575. The disparity in these results is due to the fact that the Bureau of the Census collected the data directly from the mines, while the Director of the Mint obtained the information from mints, assay offices, private refineries, and other sources. The quantities and values reported by the Director of the Mint represented the refined product, a portion of which may have been mined during the preceding year; and, moreover, since a portion of the product reported by the Bureau of the Census as mined during 1902 would be included in the report of the Director of the Mint for the following year, the totals for the two offices for the same year can not agree.

The increase that has occurred in the production of the different minerals during the thirteen years covered by Table 2 is referred to in the discussion of the statistics for each mineral on pages 393 to 1071. Reference should be made to these separate reports for more detailed information.

As no statistics for employees, wages, or expenses incident to the production of cement, clay, feldspar, flint, rutile, borax, or slate ground as a pigment are given in the report of the Eleventh Census, it was necessary to take the production for these minerals for 1889, as shown in Table 2, from the tabulation of the mineral products of the United States, apparently prepared, in some respects, independently of the regular census work, but presented in the introduction to the report.

The Eleventh Census did not present statistics of any character for bauxite, crystalline quartz, fuller's earth, lithium ore, magnesite, molybdenum, monazite, tungsten, or uranium and vanadium, these minerals not then being produced in commercial quantities. Silica sand which is usually the product of sandstone quarries was included under the classification of sandstones, while garnet was included in abrasives.

Decreases in 1902.—A decrease is shown in the production of minerals in 10 classifications enumerated in Table 2. The quantities and values of these are reproduced in the following statement:

Minerals showing a decrease in production in 1902.

MINERAL.	1902		1889	
	Short tons.	Value.	Short tons.	Value.
Antimony			265	$28,000
Corundum and emery	4,251	$104,605	2,245	105,565
Lithographic stone			18	243
Manganese ore	[1] 16,477	177,911	[1] 24,197	240,559
Marl	12,439	12,741	156,265	63,956
Mineral pigments, crude	35,479	360,885	36,184	463,766
Ozocerite			25	2,500
All other minerals [2]	440	14,617	3,151	73,000

[1] Long tons.
[2] Includes chrome ore, nickel and cobalt, and rutile.

There was no production of antimony in 1902 from domestic antimony ores, the entire product being obtained from the smelting of domestic hard lead ores, or from imported regulus or metal, and antimony ores. Antimony has not yet been uncovered in any of the states in sufficient quantity for development. The known deposits of the mineral are associated with other metals that so predominate as to prohibit the exploitation of antimony as such.

While there was a slight decrease in the value of corundum and emery produced in 1902 as compared with 1889, a great increase occurred in the tonnage. The average price per ton of the product decreased during the period of thirteen years nearly one-half. The manufacture of an artificial abrasive as a substitute for corundum and emery has had its effect upon the value of the natural material.

There was no production of lithographic stone in the United States during 1902, no beds having been found that furnished stone of sufficient purity or adequate size. The substitution of plates of zinc and other metals, and the importation of lithographic stone, principally from Bavaria, satisfied the demand.

The deposits of manganese ore found in the United States are combined with siliceous and phosphorous substances to such an extent that the production can not compete with the foreign ore. Moreover, the deposits are located in isolated places, where transportation facilities are inadequate. These disadvantages have resulted in a decrease in the production of domestic manganese ore as compared with the production of 1889, although the product in 1902 was the largest since 1891.

The decrease in the production of marl is due to the greater substitution since 1889 of fertilizers made of phosphate rock and other materials. About two-thirds of the production of 1902 was obtained from New Jersey and was consumed locally.

The indicated decrease in the production and value of crude mineral pigments is more apparent than real. The statistics for 1902 are to a considerable extent for the crude product, while the production shown for 1889 included the value of large quantities of refined material or manufactured paint. As a matter of fact, the mining of mineral pigments is progressing steadily.

Ozocerite (native paraffin), or a mineral closely related to it, was reported some years ago to have been found in Utah, but according to the report it could not be produced continuously in commercial quantities because it could not compete with the ozocerite imported from Austria. This Utah ozocerite constituted the production reported in 1889. It is said now to be exhausted. "Immense quantities are extracted from the crude petroleum found in the Pennsylvania and Lima (Ohio) fields."[1] This, as paraffin wax, is included in the products of petroleum refining.

The group of "all other minerals" shown in the above statement, includes chrome ore, nickel and cobalt, and rutile, but as there were only two operators reported for nickel and cobalt and one each for chrome ore and rutile, the production of the different minerals can not be shown without disclosing the operations of individual operators. All of these minerals show a decrease when compared with the production of 1889. Many deposits of chrome ore can not be mined on account of the low price at which the foreign ore is imported. There are only a few nickel ore deposits in the United States, and these can not be worked to advantage at the prices prevailing for refined nickel, and in competition with the more profitably worked nickel ore deposits of Canada. Cobalt is closely associated with the nickel in the ores from which these metals are obtained. A small production of rutile satisfies the demand. The quantity has increased, but there has been a large falling off in the value of the total product mined.

Early development.—Mining was not an important feature of the early development of the United States, and until comparatively recent years information concerning the mineral products of the country was very meager. Agriculture was the predominating industry of the entire country at the opening of the nineteenth century; later, manufactures received greatest attention in the Northern and agriculture in the Southern and Western states. Numerous exploring expeditions were conducted during the early history of the country for the purpose of locating mineral deposits. Reference is made in the reports of these expeditions, to the mineral deposits in the region of the Great Lakes and the Mississippi valley. "During the eighteenth century a number of mining operations were undertaken and carried on in different parts of the country, apparently with but little success."[2]

The history of coal mining in the United States affords a good illustration of the general development of the mining industry. In 1820 the first cargo of anthracite coal was sent to Philadelphia. The annual consumption of all coal in 1847 has been estimated at 3,000,000 tons;[3] in 1902 the production of anthracite coal amounted to 41,373,595 short tons and the production of bituminous coal to 260,216,844 short tons, making the total production 301,590,439 short tons.

The smelting of iron ore appears to have been carried on to some extent in Massachusetts as early as 1702.[3] The production of iron ore in 1840 has been estimated at more than 300,000 tons, and the production of pig iron from the ore in Pennsylvania amounted to 98,395 tons.[4] The Lake Superior region was opened in 1844 and about 800 tons of blooms were shipped from the region in 1853.[5] In 1902 the production of iron ore in Pennsylvania amounted to 822,932 long tons and in the Lake Superior region to 26,977,404 long tons, the production of the two districts amounting to 27,800,336 long tons, or 78.2 per cent of the 35,567,410 long tons reported for the United States.

Early in the nineteenth century gold was mined to some extent in North Carolina, and for a number of

[5] Ibid., page 478.

years following 1829 considerable quantities were produced throughout the Southern states. But few attempts at regular mining were made prior to 1834.[1] The discovery of gold deposits in California in 1848 gave an impetus not only to the search for precious metals, but also to mining enterprises of all kinds throughout the country.[2] The production of domestic gold in 1853 deposited at the United States Mint and its branches was valued at $55,622,051, $55,113,487 of which value was obtained from California.[3] The production for 1902, as reported by the Director of the Mint, was valued at $80,000,000.

Operations in the copper region of Lake Superior began as early as 1771, but particular attention was not directed to that field until 1844.[4] Its production of pure copper for 1854 has been estimated at 2,000 tons.[5] The production of the same region in 1902 was 171,102,065 pounds, or 26.8 per cent of the 639,033,392 pounds reported for the United States.

Mining in the Missouri lead field appears to have begun as early as 1720, but was not followed in a regular manner until 1798. By act of Congress of March 3, 1807, all the government lands containing lead were ordered to be withheld from sale, and leases were authorized instead. The issuing of leases began in 1822. After 1834 smelters and miners refused to make payments because of the great number of illegal entries of mineral land, and in 1847 Congress authorized the Land Office to sell the lands outright. In 1839 a geological survey of the lead region of the upper Mississippi valley was authorized by Congress. In 1840 the production of the upper Mississippi and Missouri regions was estimated at 14,780 tons.[6] In 1902 these regions produced 131,606 tons. The greater part of the lead product of the United States in 1902 was obtained from argentiferous ores. The history and occurrence of the various minerals in the different states are referred to in the discussion of the statistics for each state, on pages 163 to 346.

The importance of the mining industries is due not only to the magnitude of the aggregate production, but also to the great number of different minerals mined and the numerous uses to which they are applied. The development of these industries has occurred very largely since 1880, as many of the minerals enumerated in this report were not mined in commercial quantities before that year. Exclusive of coal, pig iron, copper, lead, petroleum and natural gas, stone, quicksilver, limestone for iron flux, zinc, and the precious metals, the mineral products of the country in 1880, as reported by the Geological Survey, were valued at only $37,567,133. The corresponding value for 1902 was $82,395,444—an increase of $44,828,311, or 119.3 per cent. The existing diversity of metals is largely the result of processes applied to the reduction of the minor metalliferous minerals; while the great absolute increase in quantity and value of mining products, in number of people employed and in yearly wages paid, is due mainly to the development of the major minerals, the great variety of uses to which the minor ores and the metals derived from them can be put has furnished a constant incentive to increase their production.

Table 8 presents statistics for 52 classifications of minerals. From these, however, there are obtained a large number of metals and other substances, each distinct in character, as the result of processes applied directly to the mineral or ore. There are also a multitude of other substances obtained by their use as bases for chemical combinations and manufacturing processes.

The organization of the United States Geological Survey in 1879 was the first step in the scientific investigation of the mineral deposits of the country as a whole. The general desire for information concerning the mineral resources of the country has been satisfied in part by systematic geological investigations in several of the states, beginning as early as 1823. At a still earlier period investigations were carried on by private enterprise, generally limited to minerals of well-known market value, such as iron, gold, silver, copper, and coal. The need for information concerning the location, character, and extent of the deposits of these minerals was fully appreciated by the organizers of the Geological Survey, and it is evident from the estimate submitted to Congress for the work of the office for the fiscal year ending June 30, 1881—the second year of the Survey's existence—that exhaustive preparations were made for the collection of information concerning all classes of minerals and the geological structure of the entire country.[7]

Rank of the United States in mining.—The United States holds first place in the production of most of the minerals and it is preeminent in the production of five of the great minerals that are the basis of manufactures—i. e., coal, iron, copper, lead, and gold. In the production of silver it is outranked by Mexico only. The quantities of these minerals, as far as they can be ascertained, for the principal producing countries, are given in the following table:

TABLE 3.—*Production of coal, iron ore, copper, lead, gold, and silver in the principal producing countries: 1902.*

COUNTRY.	Coal (short tons).	Iron ore (long tons).	Copper, refined[1] (long tons).	Lead, smelted[2] (short tons).	Gold[3] (fine ounces).	Silver[3] (fine ounces).

The position of the United States as the nation of first importance in the principal mining industries is so evident from an examination of Table 3 that further illustration is unnecessary. This position is due to the development of the vast mineral deposits in the United States, many of them practically unlimited; to improved mining methods and machinery; to the development and improvement of transportation facilities; and to the stimulus given the mining and quarrying industry by the increase of manufacturing and building in the country during the past twenty-five years. If a country be regarded as having natural resources of a given extent and character, it follows that an increase in the annual production of minerals in the country must result from one or both of two causes—increase in the number of productive laborers, and improvement of their productive power. Both of these causes have been operative in the United States in a very high degree as a result of the favoring industrial conditions that have obtained during the greater part of the last quarter of a century.

The use of the steam shovel in open-cut mining, the application of electricity and chemical methods and processes to all branches of mining, and of automatic machinery to the drilling and cutting of the rock and ore have been the principal improvements in the productive power of labor. The rates of wages which, as a rule, have prevailed in the mining industries have kept the supply of labor adequate to the demand, and, with a few notable exceptions, due to labor disturbances, strikes, or lockouts, there has been a constant increase in both the productive power and the quantity of labor.

Except in the case of the leading minerals enumerated in Table 3, there has been no systematic collection of statistics in all producing countries that would permit an authentic showing of the rank of each in the production of all classes of minerals. In the absence of such information, the estimates of Mr. Michael G. Mulhall are given as follows:

In point of value no country approaches the United States, but in weight of mineral Great Britain is ahead. It may be said, as regards weight, that Great Britain raises one-third, the United States one-third, and all other nations collectively one-third of the minerals of the world. The weight and value of minerals and the number of miners in 1894 were [value reduced to dollars at $4.80 the pound, Mulhall having fixed that rate in reducing the dollars to pounds]:

COUNTRY.	Million tons.	Million dollars.	Miners.	Dollars per miner.	Tons per miner.
Total	746	1,449	3,130,000	463	240
Great Britain	240	374	840,000	446	285
United States	230	451	580,000	778	[1]400
Germany	115	163	400,000	408	287
France	38	77	180,000	427	210
Other countries	123	384	1,130,000	340	110

[1] The exact number of miners is not known. * * * The rates in 1880 were even higher, viz, 440 tons per miner.

The money value of product per miner is higher in Great Britain than among other European nations, but is greatly surpassed by the ratio in the United States, perhaps because in the latter country the difficulties of extraction are less.[1]

Mr. Mulhall states further that coal is the great lever of industrial progress and constitutes 70 per cent of the total mineral production of all nations; also that the production has grown thirtyfold since 1820,[2] the showing for the two years for the leading nations being as follows:

COUNTRY.	1820	1894
Total	17,200,000	531,000,000
Great Britain, tons	12,500,000	188,300,000
United States, tons	500,000	152,500,000
Germany, tons	1,500,000	99,000,000
Other countries, tons	2,700,000	91,200,000

The production of coal in the United States in 1902 was 301,590,439 short tons, exceeding that of Great Britain by 47,243,992 tons. In the production of iron

[1] Industries and Wealth of Nations, by Michael G. Mulhall, edition of 1896, pages 34 and 35.

[2] Ibid., page 35.

ore Mr. Mulhall gives the United States first rank in 1894, with a production of 17,000,000 tons, as compared with 12,400,000 tons for Great Britain and Germany, respectively, which shared the second place.[1] He gives the United States the third place in 1894 in the production of gold, and the second place in the production of silver, assigning the first place to Spanish America, with a production valued at £9,900,000, as compared with £6,100,000 for the United States.[2] The production of pig iron in the United States in 1901 was 15,878,354 gross tons, as compared with 7,928,647 gross tons in Great Britain and 7,736,663 gross tons in Germany, the production of the United States thus exceeding the combined production of the two countries by 213,044 gross tons. The statistics of 1902 for Great Britain and Germany are not available, and therefore no comparative figures for that year can be given. The production of silver in the United States in 1902 was valued at $71,757,600 (coining value), as compared with $108,343,000 for Spanish America.

Increase since 1880.—The following table shows the relative increase in population and in value of manufactures, agricultural products, and mineral products since 1880, as shown in the Tenth, Eleventh, and Twelfth censuses:

TABLE 4.—INCREASE IN POPULATION AND IN VALUE OF AGRICULTURAL PRODUCTS, MANUFACTURES, AND MINERAL PRODUCTS: 1880 TO 1900.[1]

YEAR.	Population.	Agricultural products.	Manufactures.	Mineral products.	PER CENT OF INCREASE.			
					Population.	Agriculture.	Manufactures.	Mining.
1900	76,149,386	$4,717,078,021	$13,014,287,498	[2]$796,819,729	20.9	91.7	38.9	94.0
1890	62,979,766	2,460,107,454	9,372,437,283	410,760,770	25.6	11.2	74.5	63.0
1880	50,155,783	2,212,540,927	5,369,579,191	251,967,055				

[1] Exclusive of Hawaii.

[2] For the calendar year 1902.

While the comparison of the population and of manufactures and agriculture in Table 4 is limited to twenty years and of mining industries to twenty-three years, it covers a period that has been quite remarkable for the development of the mining industries. The value of the mineral products increased for the whole period 216.2 per cent, as compared with an increase of 51.8 per cent for population, 142.4 per cent for manufactures, and 113.2 per cent for agriculture. In 1880 for every dollar of mineral products there were $21 of manufactures and $9 of agricultural products. In 1900 the ratios were $16 and $6 for manufactures and agriculture, respectively, to $1 for mineral products. In 1880 the per capita values of the products of manufactures, agriculture, and mining were $107, $44, and $5, respectively. By 1900 these values had increased to $171, $62, and $10, respectively.

In the absence of annual census data, yearly totals, as compiled by the United States Geological Survey, are presented in Table 5, to show the annual growth of the various industries. These totals include value of product for salt, pig iron, bromine, refined gold and silver, zinc white, and other manufactured products not taken at the census of 1902, as well as mineral waters which are not the product of regular mining operations as defined by the Bureau of the Census.

[1] Industries and Wealth of Nations, by Michael G. Mulhall, edition of 1896, page 35.

[2] Ibid., page 36.

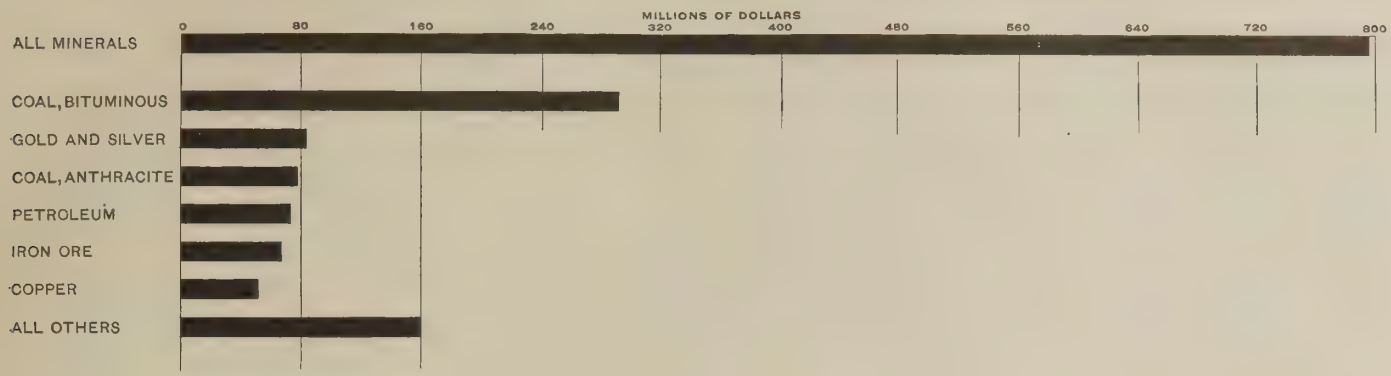
TABLE 5.—*Mineral products: 1892 to 1902.*

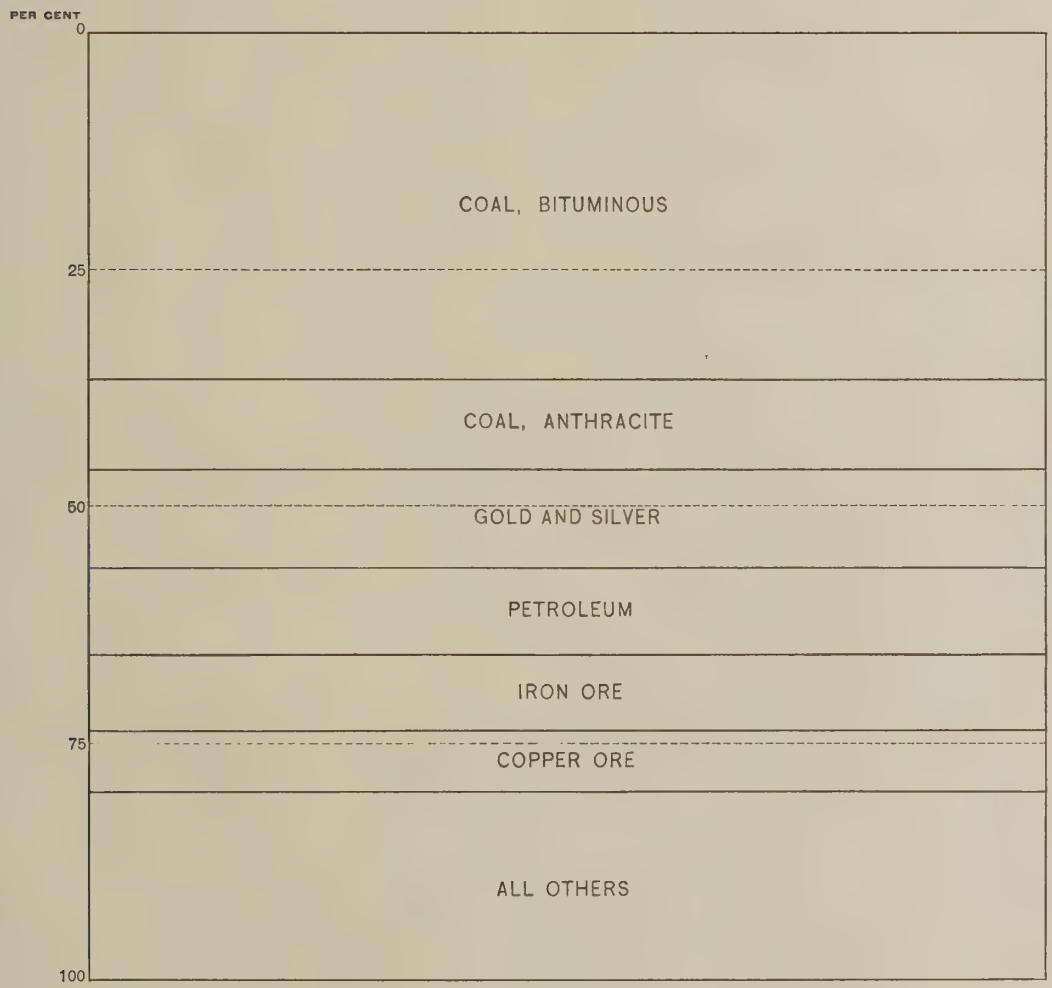
[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Total.	Value of nonmetallic mineral products.	Value of metallic products.	Estimated value of mineral products unspecified.
1902	$1,260,639,415	$617,380,831	$642,258,584	$1,000,000
1901	1,086,584,851	567,318,592	518,266,259	1,000,000
1900	1,063,678,053	512,252,767	550,425,286	1,000,000
1899	972,208,008	445,428,431	525,779,557	1,000,000
1898	698,596,788	353,848,520	343,748,268	1,000,000
1897	631,237,074	327,705,927	302,531,147	1,000,000
1896	622,814,265	333,954,110	287,860,155	1,000,000
1895	620,652,170	338,172,239	281,479,931	1,000,000
1894	527,079,279	307,714,785	218,382,494	1,000,000
1893	574,464,724	323,257,318	250,207,406	1,000,000
1892	648,895,031	339,958,842	307,936,189	1,000,000

With the exception of the two years from the close of 1892 to the close of 1894, there has been a yearly increase in the value of product. The average annual increase during the past eight years has been $91,695,017. It will be noted that the production for 1902 exceeds by $463,812,998 the $796,826,417 reported by the census as the value of the products of mines, quarries, and petroleum and natural-gas wells. This excess is explained almost entirely by the difference between the value of the crude ore and the value of the metals smelted and refined from them, such as iron, gold and silver, copper, and lead and zinc. Thus, the ore classed as copper ore by the census method was valued at $51,178,036, while the value of the refined copper contents of all ores as reported by the Survey was $76,568,954. Again, the

DIAGRAM I.—VALUE OF PRODUCTS OF PRINCIPAL MINERALS AND PROPORTION EACH BEARS TO TOTAL: 1902.





value of the gold and silver as reported by the Bureau of the Census was $82,482,052 at the mine, these figures being exclusive of Alaska; but the coining value of the gold and silver reported by the Survey amounted to $151,757,575, and, in addition, platinum to the value of $1,814 was obtained. The Bureau of the Census reported iron ore valued at $65,465,321; the Survey placed in its totals for mineral products the value of the pig iron made in 1902, $372,775,000. The lead and zinc ores were valued by the Bureau of the Census at $14,600,177; the value of the refined metal was reported by the Survey at $36,765,596. These differences are explained in detail in the report for the several minerals.

Leading minerals.—While a great variety of minerals are included in the $796,826,417 reported as the value of the mining products at the Twelfth Census, the production of a few of the leading ones, such as coal, iron, copper, lead and zinc, petroleum and natural gas, and the precious metals, constitutes a large percentage of the total, and the great growth in the mining of these has been the principal cause of the increase in the number of people employed and in the value of products. The comparative importance of the principal minerals, as determined by the percentage that the totals for each form of the aggregates for the United States, is shown in the following table:

TABLE 6.—SUMMARY FOR LEADING MINERALS, AND PERCENTAGE EACH FORMED OF TOTAL: 1902.

	Number of mines, quarries, and wells.	Number of operators.	WAGE-EARNERS.		Supplies and materials, and miscellaneous expenses.	Value of product.
			Average number.	Wages.		
All minerals	151,516	46,858	581,728	$369,959,960	$195,586,680	$796,826,417
Coal, anthracite and bituminous	5,986	4,528	350,329	$220,198,401	$63,621,400	$367,032,069
Per cent of total	3.9	9.6	60.2	59.5	32.5	46.1

Per cent of total	0.1	0.3	4.5	5.7	6.4	6.4
Gold and silver	2,992	2,992	36,142	$36,077,492	$22,057,297	$82,482,052
Per cent of total	2.0	6.4	6.2	9.8	11.3	10.4
Iron ore	525	332	38,851	$21,531,792	$17,263,322	$65,465,321
Per cent of total	0.3	0.7	6.7	5.8	8.8	8.2
Lead and zinc ore	559	557	7,881	$4,329,271	$4,603,658	$14,600,177
Per cent of total	0.4	1.2	1.4	1.2	2.4	1.8
Petroleum and natural gas	134,477	31,489	22,230	$16,178,640	$46,112,750	$102,265,602
Per cent of total	88.8	67.2	3.8	4.4	23.6	12.8
Stone[1]	5,764	5,470	71,156	$37,515,907	$14,716,601	$70,462,438
Per cent of total	3.8	11.7	12.2	10.1	7.5	8.9
All other minerals	1,069	1,346	29,132	$12,977,052	$14,731,012	$43,340,722
Per cent of total	0.7	2.9	5.0	3.5	7.5	5.4

[1] Includes limestones and dolomites, marble, sandstones and quartzites, siliceous crystalline rocks, slate, and silica sand.

The mining of the seven groups of leading minerals shown separately gave employment to 95 per cent of the wage-earners, and their production formed 94.6 per cent of the total production.

Less than one-tenth of the mine operators of the country were engaged in the production of ores, and their mines gave employment to less than one-fourth of the wage-earners, the value of their product being less than one-third of the total value of products.

To assist in a further analysis of the totals, and to show the concentration in certain lines of production, the statistics have been grouped according to the character of the minerals and of the metals obtained from the ore or the uses made of them. The classification of this character, made in the annual reports of the Geological Survey on the mineral resources of the United States, has, for the purpose of uniformity, been adopted by the Bureau of the Census.

A comparatively small proportion of the mineral products of the country can be classed as metalliferous, much the larger proportion consisting of coal, petroleum, natural gas, stone, borax, gypsum, phosphate rock, and other substances not of a metallic nature. In the following table the statistics are segregated so as to show the totals for metallic and nonmetallic substances:

TABLE 7.—*Summary for metallic and nonmetallic products: 1902.*

	Total.	Metallic.	Nonmetallic.
Number of mines	151,516	4,280	147,236
Number of operators	46,858	4,081	42,777
Salaried officials, clerks, etc.:			
Number	38,128	8,138	29,990
Salaries	$39,020,552	$9,948,335	$29,072,217
Wage-earners:			
Average number	581,728	110,404	471,324
Wages	$369,959,960	$84,046,224	$285,913,736
Contract work	$20,677,938	$1,371,921	$19,306,017
Miscellaneous expenses	$71,771,713	$17,168,321	$54,603,392
Cost of supplies and materials	$123,814,967	$39,639,703	$84,175,264
Value of product	$796,826,417	$215,453,587	$581,372,830

TABLE 8.—SUMMARY FOR MINERALS GROUPED ACCORDING TO CHARACTER OF ORES AND USES: 1902.

All other minerals[1]	6	6	1	240	15	10,411	825	950	3,432	49,256

[1] Includes operators as follows: Chrome ore, 1; magnesite, 1; molybdenum, 1; nickel and cobalt, 2; rutile, 1.

As elsewhere explained, some of the substances included in the general groups by the Geological Survey are not covered by the census of mines and quarries. Further, the assignment of the different minerals to the respective groups should not always be accepted as an exact segregation. For instance, petroleum is assigned to the group of fuels, but a considerable proportion of the refined product is used for other purposes. In like manner, the group of "structural materials" includes all stone, although some sandstone is crushed and used in the pulverized form in the manufacture of glass, and a considerable amount of limestone is used for iron flux, for the manufacture of lime, and for roadmaking. There is, in fact, but slight connection between the totals for any of the groups other than their general relation to the industrial progress of the country. It is interesting, however, to note the proportion which each of these groups contributes to the general totals for all mines and quarries. These proportions are shown in Table 9.

DIAGRAM II.—PRODUCTION OF PRINCIPAL MINERALS, BY STATES AND TERRITORIES: 1902.

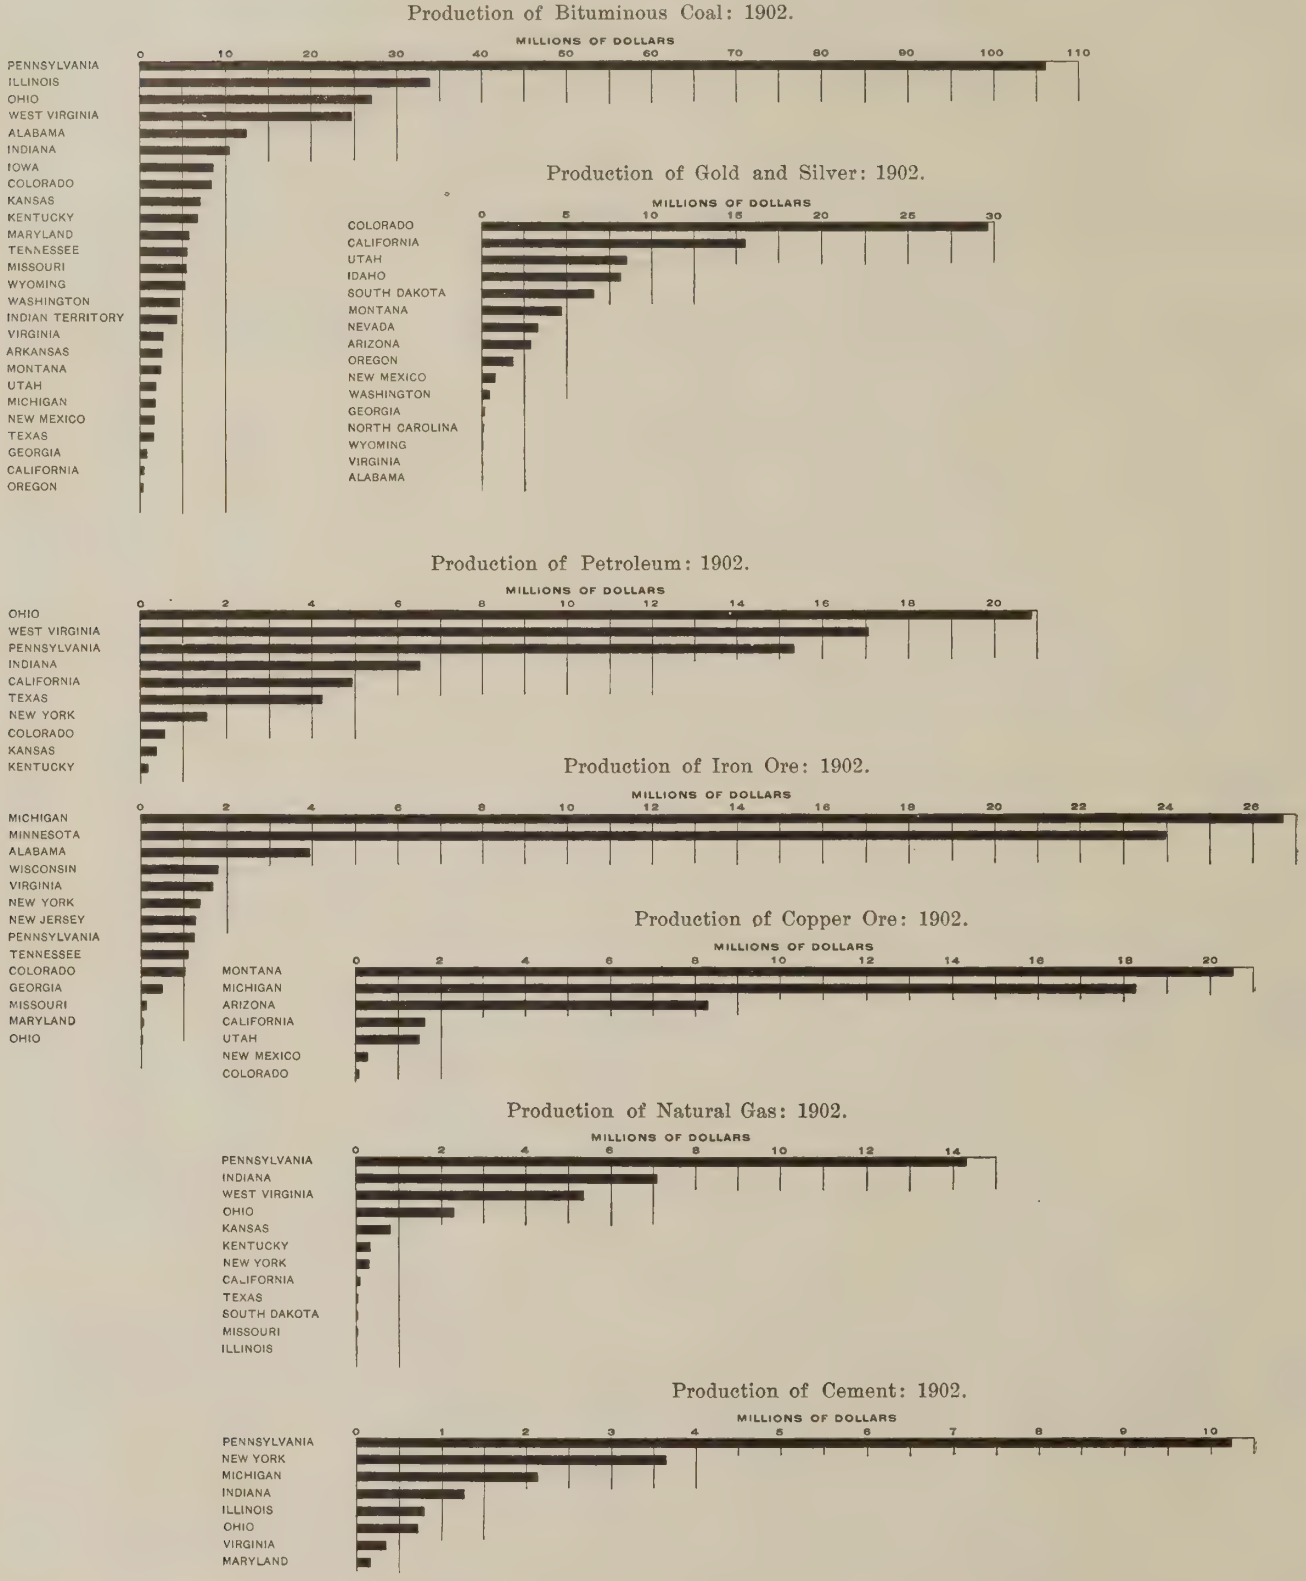

DIAGRAM II.—PRODUCTION OF PRINCIPAL MINERALS, BY STATES AND TERRITORIES: 1902—Continued.

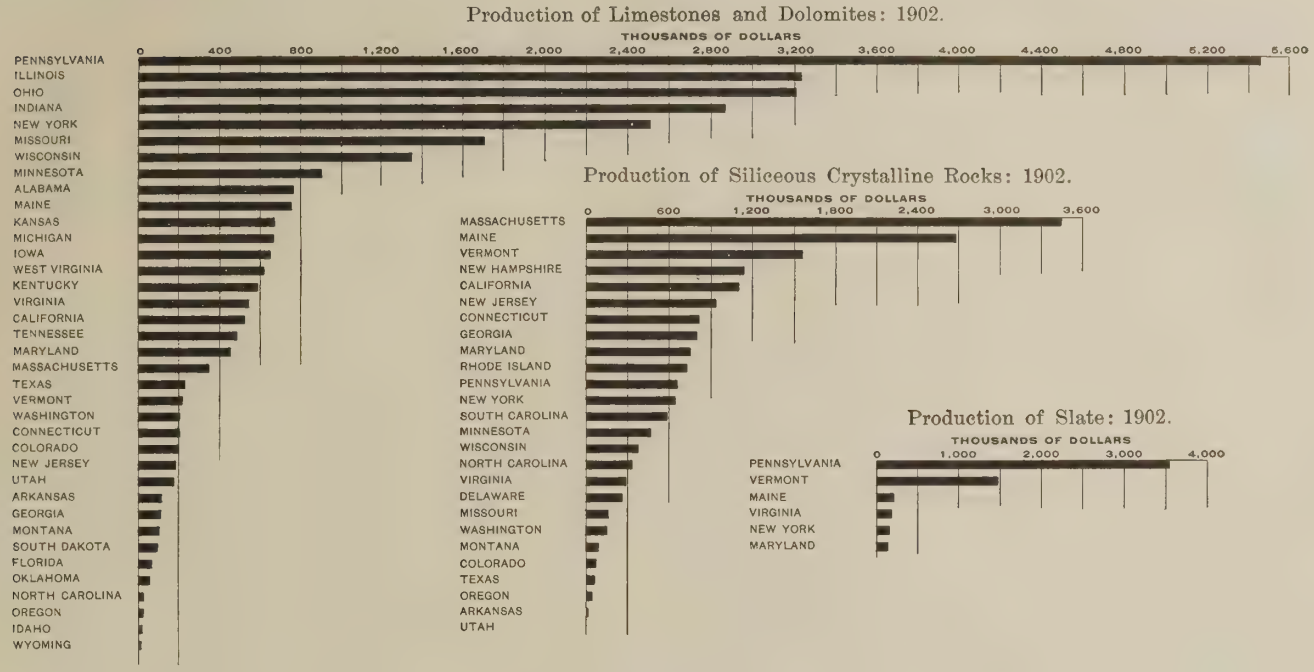

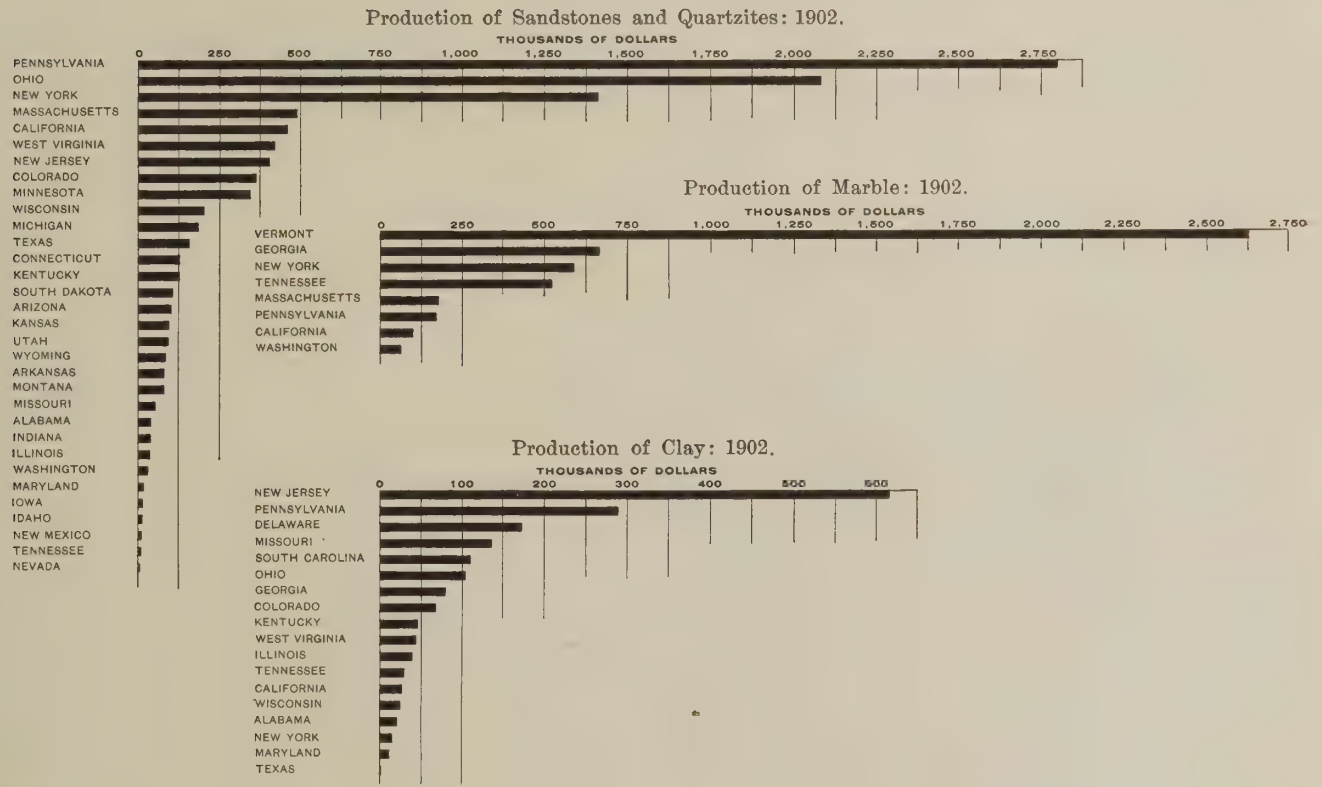

TABLE 9.—PERCENTAGE EACH GROUP OF MINERALS FORMS OF TOTAL: 1902.

Miscellaneous	0.2	1.5	0.9	0.8	0.4	0.3	0.1	0.3	0.3	0.4

[1] Less than one-tenth of 1 per cent.

Fuels are by far the most important group of minerals. Their production gave employment to 64.1 per cent of the wage-earners, and the value of the products belonging to the group formed 58.9 per cent of the total value reported for all minerals. The production of coal alone gave employment to more than 100,000 wage-earners in excess of the number employed in the production of all other minerals combined; the wages paid by operators of coal mines exceeded those paid by all other operators by $70,436,842; and the value of the annual production of coal was within $62,762,279 of the value of all other minerals.

The metalliferous minerals rank next in importance. The value of the crude metallic products constituted 27 per cent of the total value of products, and their production gave employment to 19 per cent of the wage-earners. This group is composed of the various ores and metals enumerated under the term "metallic" in Table 9. Of these, iron ore is the most important from the standpoint of wage-earners, and gold and silver the most important measured by value of products. Of the 110,404 wage-earners reported for the group, 38,851, or 35.2 per cent, were employed in the production of iron ore, and they received $21,531,792, or 25.6 per cent of the total wages for the group. The value of the iron ore produced was reported at $65,465,321, or 30.4 per cent of the total for the group. The gold and silver was valued at the mine at $82,482,052, which is 38.3 per cent of the total for the group, exceeding the value of the iron ore by $17,016,731. But on the other hand the number of wage-earners engaged in the production of iron ore exceeded the number for precious metals by 2,709. The wages, however, for precious metals exceeded those paid for iron ore by $14,545,700.

Structural materials ranked third in importance. This group includes marble, granite, and other stones and embraces a great variety of products. The production of structural materials gave employment to 14.8 per cent of all wage-earners engaged in the mining industries, and the wages of these employees formed 12 per cent of the total wages. The value of structural materials quarried amounted to 12.1 per cent of the total value of the products of all mining operations.

While the other groups enumerated in Table 9—abrasive materials, chemical materials, pigments, and miscellaneous substances—are important from the standpoint of the variety of their products and the uses made of them, the wage-earners engaged in their production and the value of their products form a very small proportion of the totals for all minerals.

Mineral products by states.—The contribution of each mineral and group of minerals to the aggregate for the United States having been considered, it may be of interest to examine the contribution of each state to this aggregate, irrespective of the character of the minerals produced. Mineral production is necessarily concentrated in the states containing the most extensive and most favorably situated deposits. The deposits located conveniently for utilization of the products have been developed to the detriment of those in less favored sections. These conditions have stimulated the development of the mineral deposits in certain states, and it frequently occurs that practically the entire product of a state is represented by a single mineral. The totals for the different states are presented in Tables 10 and 11, and the proportions are graphically shown in the accompanying diagram. Table 10 shows the general totals for all minerals in each state and territory, while Table 11 presents the value of the mineral products in each state and territory in comparison with the population and the gross value of the products of agriculture and manufactures as reported at the Twelfth Census, and also the rank of the state and the per capita value for each class of products. In addition to the gross value of products this table shows the net value of the manufactured products; i. e., the gross value less the cost of materials purchased in a partially manufactured form.[1]

[1] For method of computing net product, see Twelfth Census, Report on Manufactures, Part I, page cxxxix.

DIAGRAM III.—VALUE OF ALL MINERAL PRODUCTS, AND VALUE OF EACH GROUP: 1902.

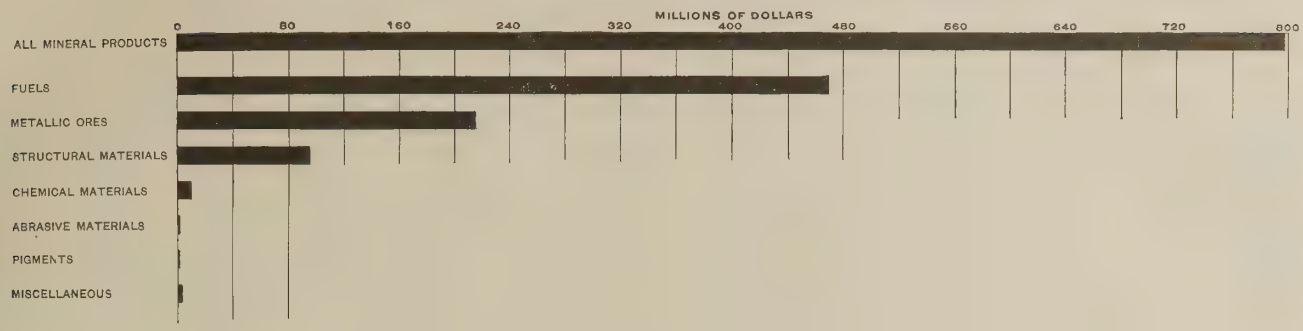

DIAGRAM IV.—PRODUCTION OF PRINCIPAL MINERALS: 1902.

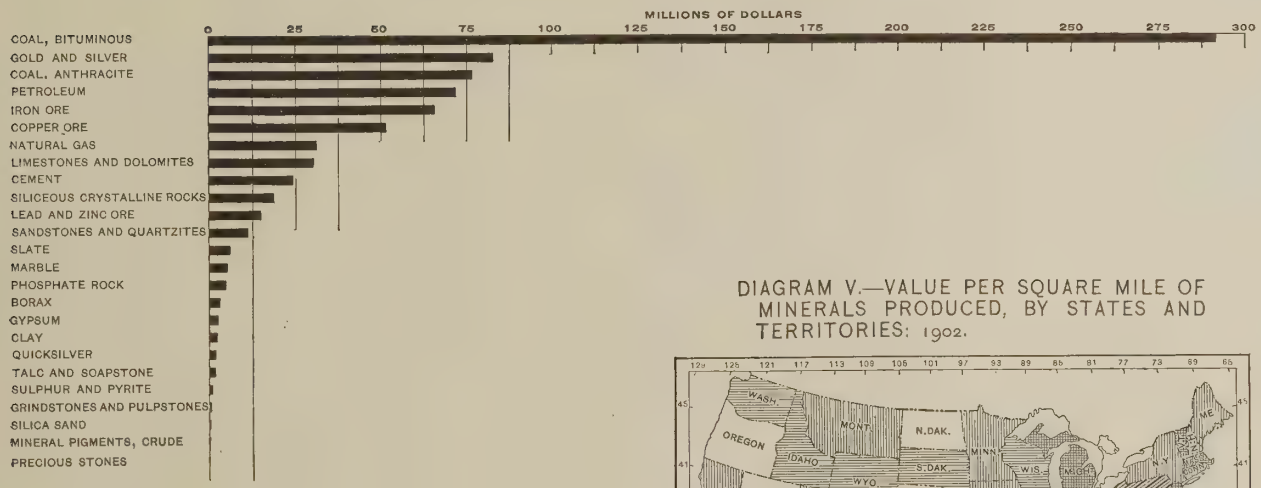

DIAGRAM V.—VALUE PER SQUARE MILE OF MINERALS PRODUCED, BY STATES AND TERRITORIES: 1902.

[2] Less than 50 cents.

While the mineral products of a state are dependent primarily on the extent and character of the deposits, their development is controlled by a number of factors, such as the proximity of the ore to the surface, nearness to markets, the extent and character of transportation facilities, the supply of labor and power, and the application of new and improved machinery and methods. The application of the steam shovel and other labor-saving devices in open cut iron mining, and of the cyanide process to the reduction of the precious metal bearing ores, are notable examples of the improvements in machinery and methods. Manufactures are largely dependent upon mineral products for fuel and raw material and their development must necessarily be preceded by a corresponding increase in mineral products. A similar, though not so intimate, interdependence exists between the products of agriculture and manufactures. The three industries are closely related, and, in the absence of far-reaching transportation facilities, there might be a certain harmony between the products of each in the different states, but the extensive, rapid, and easy means of transportation now available make it possible to utilize the minerals and agricultural products of one state in the manufactures of another, either adjoining or distant; there is, therefore, very little, if any, agreement in the relative rank of the different states in the three industries.

Accepting as comparable the statistics of population, agriculture, and manufactures for the Twelfth Census, which covered the fiscal year ending May 31, 1900, and the statistics for mineral industries, which covered the calendar year 1902, it appears that, as a rule, the value of the mineral products of the several states is far below the value of the products of agriculture and of manufactures, respectively. But in the states of Idaho, Nevada, and Wyoming and in Indian Territory the value of minerals exceeded the value of the products of manufactures; and they were in excess of the products of agriculture in the states of Colorado, Pennsylvania, and West Virginia and in Arizona and Indian Territory. Mineral products were reported for all of the states and territories with the exception of the District of Columbia and Mississippi. In many of the states, however, the value of the minerals reported was insignificant as compared with the value of the products of agriculture and manufactures. In several states—Delaware, Louisiana, Nebraska, North Carolina, North Dakota, and Rhode Island—and in the territory of Oklahoma they were less than $1,000,000, while the value of the products of agriculture and manufactures, respectively, in every state and territory exceeded $1,000,000, with the exception of the agricultural products reported for the District of Columbia. While there is not the same intimate relationship between population and mining that exists between population and agriculture and between population and manufactures, the per capita value of the mineral products has been included in Table 11 for the purpose of making a comparative showing.

Pennsylvania, which ranked second in population and manufactures, and eighth in agriculture, was the leading mining state in 1902, both in the number of

wage-earners employed and in the value of products. Its high rank was due to the production of anthracite and bituminous coal, the wage-earners reported for the coal mines forming 84.7 per cent of the 190,935 reported for all mines in the state, and the products of such mines forming 76.9 per cent of the total product of $236,871,417. The position of Pennsylvania as the leading mining state was most pronounced. Out of a total of 581,728 wage-earners engaged in mining in the United States, Pennsylvania reported 190,935, or 32.8 per cent, who received as wages $114,122,437, or 30.8 per cent of the $369,959,960 reported as the total. The value of the state's production was equally high, being $236,871,417, or 29.7 per cent of the $796,826,417 reported for the United States. Practically one-third of the whole mining industry of the United States, as measured by the persons employed and the value of products, was confined to this state. While it is true that the exploitation of its enormous coal deposits has been responsible for Pennsylvania's position as the leading mining state and that this industry has assumed overshadowing proportions, it is also true that the state has produced a large variety of minerals. Of the 52 classes of minerals reported 23 were found in Pennsylvania, the state being exceeded in this respect only by California, with 26 classes, and by Virginia, with 24.

New York, which stood first in population and in manufactures and fourth in agriculture, was thirteenth in mineral products. The state's mineral industry, employed 1.6 per cent of the wage-earners, paid them 1.4 per cent of the wages, and produced 1.7 per cent of the total value of products. The 5 leading mining industries of New York were cement, limestones and dolomites, petroleum, sandstones and quartzites, and iron ore, ranking in the order named. For each of these classes a production of over $1,000,000 was reported, and the 5 together showed a production of $10,462,663, or 78.4 per cent of the total for the state.

Ohio, which ranked fourth in population, third in agriculture, and fifth in manufactures, held the second position in value of mining products. The total value reported for the state was $57,186,922. Of this amount the product of coal mines formed $26,953,789, or 47.1 per cent. The state also held third place in the number of wage-earners, the coal mining giving employment to 25,963, or 69.8 per cent of the 37,173 reported for the state. Next to coal, petroleum is Ohio's chief mining industry, the two combined contributing over four-fifths of the state's mineral wealth.

Michigan, ninth in population, tenth in manufactures, and thirteenth in agriculture, ranked third in mineral products. With 40.8 per cent of the total value of the iron ore output of the United States credited to it, Michigan was the leading producer of this mineral, which was the chief product of its mines. This industry claimed 14,456 wage-earners, or 45.2 per cent of the 31,951 employed in all the mines of the state, yielded them in wages $9,132,763, or 45.4 per cent of the total of $20,103,616; and the product itself was valued at $26,695,860, or 53.2 per cent of the $50,157,358 representing the total value of the output. After iron ore, Michigan's most important mineral product was copper ore, its output being valued at $18,247,207, a figure that was exceeded by Montana only. It will be noted that these two ores together were credited with a total value of $44,943,067, or 89.6 per cent of the total value of the mineral output of the state.

West Virginia, twenty-eighth in population and agriculture, and thirty-first in manufactures, was fourth in mineral products. The coal mines of the state gave employment to 23,914, or 79.7 per cent of the wage-earners, and their products formed $24,748,658, or 51.2 per cent of the total value of mineral products reported for the state. In the production of coal, West Virginia ranked fourth, being outranked only by Pennsylvania, Illinois, and Ohio, and the high ranking of these states as mineral producers was due, either wholly or in great part, to this industry. After coal, West Virginia's leading minerals were petroleum, with an output valued at $17,040,317, and natural gas, valued at $5,390,181. These three industries together account for 97.5 per cent of the reported mineral values of the state. It is interesting to contrast this condition with that of Michigan, the one producing, to an almost exclusive extent, fuels, and the other an enormous preponderance of ores.

Colorado, thirty-first in population, thirty-sixth in agriculture, and twenty-seventh in manufactures, ranked fifth in mineral products. This high position was due almost exclusively to the precious metals of the state. The gold and silver produced in 1902 were valued at $29,655,974, forming 73 per cent of the total production of the state, and 36 per cent of the total value of these minerals in the United States, and thus exceeding California's production of gold and silver, valued at $15,473,091, by almost 91.7 per cent. This industry in Colorado gave employment to 11,200 wage-earners, or 54.6 per cent of the 20,519 engaged in mining in the state, and returned to them as wages $11,726,123, or 62.1 per cent of $18,874,836, the total amount paid in wages. Bituminous coal with a value of production amounting to $8,397,812 ranked second in Colorado's mining industries, and iron ore was third with a product valued at $1,084,424.

Illinois, third in population and in manufactures, and second in agriculture, was sixth in rank as a mining state. Here, also, bituminous coal was the leading mineral. Its production employed 36,617 wage-earners, or 90.4 per cent of the 40,523 wage-earners engaged in mining in the state, and paid them $24,876,201, or 92.2 per cent of the $26,986,397 paid in wages in the state; and the product itself was valued at $33,945,910, or 88.8 per cent of the $38,234,410 reported as the total

DIAGRAM VI.—VALUE OF MINERALS PRODUCED IN EACH STATE AND TERRITORY: 1902.

States with a production less than $300,000 not shown.

value of the state's mineral output. Limestones and dolomites, with a product valued at $3,232,123, constituted the industry second in importance.

California, twenty-first in population, fourteenth in agriculture, and twelfth in manufactures, ranked seventh in the value of mining products, but led the states in the variety of the minerals, reporting production in 26 of the 52 classes. It was unique also in the fact that at least two of its minerals, viz, chrome ore and magnesite, were mined nowhere else in the Union, and that in others, such as quicksilver and borax, its lead was so great that it may almost be said to have stood alone. The leading mineral products in California were gold and silver, valued at $15,473,091; petroleum, $4,873,617; borax, $2,370,994; copper ore, $1,599,663; quicksilver, $1,295,740; and siliceous crystalline rocks, $1,137,679. The state had 6 distinct mineral classifications, for each of which an output of over $1,000,000 was reported. Its leading mineral product, gold, although of less value than when it won for the state its title of "Golden," is still of greatest importance. In the mining of gold and silver there were employed 7,989 wage-earners, or 61.6 per cent of the state's 12,964 wage-earners engaged in mining; and these received as wages $7,101,003, or 64.3 per cent of the $11,050,666 paid as mining wages. Of the state's total output of all minerals, valued at $28,870,405, the precious metals contributed $15,473,091, or 53.6 per cent. California's production of gold and silver amounted to 18.8 per cent of the total value of the products of this industry in the United States, and was second only to that of Colorado. California produced 6.8 per cent of the country's value of petroleum; 99.5 per cent of borax; 3.1 per cent of copper ore; and 83.6 per cent of quicksilver.

Montana owes its rank as eighth among mining states almost entirely to its enormous production of copper ore, although the precious metals and bituminous coal, with outputs valued at $4,688,536 and $2,443,447, respectively, contributed about one-fourth of the value of the state's mineral products. The output of copper ore, valued at $20,563,353, or 40.2 per cent of the total for this industry, formed 72.8 per cent of the $28,265,085 reported as the total value of the state's mineral production, afforded employment to 6,388 wage-earners, or 60.6 per cent of the 10,539 mining wage-earners, and paid them $7,339,773, or 62.1 per cent of the total of $11,812,150 expended for wages. That Montana is preeminently a mining state is discernible at a glance when it is noted that in population, agriculture, and manufactures it ranked forty-third, thirty-seventh, and thirty-fourth, respectively.

Indiana, closely pressing Montana, ranked ninth in the products of mines and quarries, a position which is the result of the value of its fuel products, its leading mineral resources being bituminous coal, natural gas, and petroleum. Structural materials, as represented by limestones and dolomites and cement, also contributed much to the state's mineral wealth. The five classes of products just mentioned show a value amounting to $28,159,545, which is 99.8 per cent of the total for the state, $28,224,760. The total was distributed among the five as follows: Bituminous coal, $10,399,660, or 36.8 per cent; natural gas, $7,081,344, or 25.1 per cent; petroleum, $6,526,622, or 23.1 per cent; limestones and dolomites, $2,865,691, or 10.2 per cent; and cement, $1,286,228, or 4.6 per cent. Of the 16,473 wage-earners engaged in mining in Indiana, 10,593, or 64.3 per cent, were employed in extracting coal, receiving in wages $7,396,425, which is 68.9 per cent of the $10,729,767 paid in mining wages in the state. The state ranked ninth in agriculture, while in population and manufactures it was eighth.

Minnesota, nineteenth in population, eleventh in agriculture, and thirteenth in manufactures, was tenth in mining. The total value of its mining production was $25,729,545, of which $23,989,227, or 93.2 per cent, was credited to iron ore. There were but 6 of the different classes of minerals reported for the state, and none except iron ore had an output valued at more than $1,000,000. Of the 9,760 wage-earners employed in the state's mines, 8,256, or 84.6 per cent, were credited to the iron ore industry, receiving 84.1 per cent, or $5,376,933 of the $6,391,184 paid out as the total wages. In this industry Minnesota was exceeded by Michigan only, contributing 36.6 per cent of the total value as compared with Michigan's 40.8 per cent.

Mineral products by geographic divisions.—The mining statistics according to states and character and uses of minerals show the great preponderance of certain states and of a few ores in the forming of the totals for the country. The concentration of all, or any one, of the three productive industries—agriculture, manufactures, and mining—in any particular locality is indicative of the predominating industrial characteristics of that locality. The physical and industrial features of groups of neighboring states are in many cases so similar that a distinct advantage in clearness of presentation is realized by combining such states and treating the groups as geographic units. Such a geographic summarization brings together groups of neighboring states, each group embracing from 8 to 12 states and territories, in which the prevailing industrial conditions and the mineral and other natural resources are in many respects similar. This is especially true in the mining industries. The five geographic groups—North Atlantic, South Atlantic, North Central, South Central, and Western—are deemed sufficient to illustrate this similarity. Table 12 shows the value of the products of manufactures, agriculture, and mining for each of the geographic subdivisions and the rank of each in each industry, and also the population of each group, with its rank in population.

TABLE 12.—POPULATION, VALUE OF AGRICULTURAL PRODUCTS, MANUFACTURES (GROSS AND NET), AND MINERAL PRODUCTS, WITH RANK OF EACH, BY GEOGRAPHIC DIVISIONS.

DIVISION.	POPULATION, 1900.		AGRICULTURAL PRODUCTS, 1900.		MANUFACTURES, 1900.				MINERAL PRODUCTS, 1902.	
					Gross value.		Net value.

[1] Exclusive of Alaskan coal and Hawaiian stone products.

The table enables the reader to grasp at a glance the leading industries of the different sections of the country. It should be borne in mind, however, that this treatment does not take into consideration the production of the fisheries, which in some sections assumes proportions of considerable magnitude.

The leading group in the mineral industries is the North Atlantic, with a value of products amounting to 34.4 per cent of the total. This group is followed, in order, by the North Central, with 31.6 per cent of the total; the Western, with 18.7 per cent; the South Atlantic, with 9 per cent; and the South Central, with 6.3 per cent.

The North Atlantic division owes its ranking position primarily to the enormous coal production of Pennsylvania. Illinois and Ohio, with their output of coal, and Minnesota and Michigan, with their iron and copper ores, explain the second rank held by the North Central division. The Western group ranks third chiefly because of Colorado's gold and silver and bituminous coal, and because of California's production of the precious metals, petroleum, borax, etc.

II.

DEVELOPMENT WORK.

For census purposes all mines, quarries, and petroleum and natural-gas wells were classed as either "productive" or "unproductive," the latter being regarded as engaged in development work. Development work is an incident in the operation of all mines and quarries, but there were 4,126 properties reported in which the work during 1902 was entirely of this class. The labor employed in this development work and the expenses incident to it form a part of the mining operations of the country, and should be included in the statistics; but, in order to preserve harmony among the items—number of employees, wages, expenses, and quantity and value of product—the productive and unproductive classes have been treated separately. In making this separation it was necessary to classify as "development work" all mines for which labor, but no product, was reported; and it is probable that some of them were not engaged in development work at all, but were idle, the employees being engaged simply in preserving and caring for the property. It is difficult to trace the line of demarcation between development work and other mining operations. A large proportion of the employees of a mining company may be engaged in sinking new shafts or making new tunnels to reach undeveloped deposits, and yet if even a small production is reported the mine is necessarily classed as a producing property; but, on the other hand, the sinking of new shafts may be only incidental to the working of new deposits from which valuable products are obtained. The employees engaged in surveying, drilling wells, clearing ground, building flumes, making shafts or tunnels, and, in fact, in doing any work except the actual digging and delivery of the ore, may, on a strict interpretation, be classed as doing development work. Undoubtedly a great deal of development and exploiting work was done during the year on properties that were idle and apparently abandoned at the time they were visited by the census agent. It was impracticable to obtain any information concerning the work on such mines, and therefore the statistics for development work can not be accepted as covering the entire field. A general summary of the statistics for the mines, quarries, and wells classed as "productive" and "unproductive" is given in Table 13.

TABLE 13.—PRODUCTIVE AND UNPRODUCTIVE MINES, QUARRIES, AND WELLS: 1902.

Unproductive	47	46	34	29,110	146	82,194	808	5	10,484	23,497

The 4,126 mines and quarries classed as unproductive were controlled by 3,650 operators. There were, on the average, 13,638 wage-earners employed by these operators during the year, and the total annual wages amounted to $12,801,935. The development work done on contract during the year amounted to $2,664,526; and, in addition, $2,693,902 was paid as salaries, and $7,475,461 was spent for miscellaneous expenses, supplies, and materials, making a total of $25,635,824 expended in development work, for which there was absolutely no return in production. Of this total, $21,551,358, or 84.1 per cent, was reported for the precious metals, the amount being expended by 3,252 operators. The remainder, $4,084,466, or 15.9 per cent, was expended by 398 operators engaged in exploiting and development work for a variety of minerals. Table 14 presents the statistics for development work in each state and territory.

TABLE 14.—DEVELOPMENT WORK, BY STATES AND TERRITORIES: 1902.

III.

LIMITATIONS OF THE USE OF CENSUS STATISTICS OF MINING.

The uses that can properly be made of the census figures are discussed in the reports on the different minerals, and also in different sections of this summary and analysis. The limitations imposed are similar to those which appear in connection with the use of the statistics of manufactures discussed in detail in Part I of the report on manufactures of the Twelfth Census.

The statistics of mines, quarries, and petroleum and natural-gas wells can be accepted as indicating the growth and relative importance of the states, and of the different sections of the country in the production of the different minerals. When possible the figures have been presented in comparative tables which embrace data reported at previous censuses. The figures can be used to ascertain the quantity and the value of the different minerals produced, the average number of persons employed in their production, and the total amount paid in wages in the different states at different census periods. The general condition of the mining industries of the country and the extent to which the mineral deposits in the different states have been developed can likewise be determined. The limitations of the use of these statistics may be summarized as follows:

1. The figures show only the total production for a period of twelve months. They do not indicate the character or extent of the mineral deposits or the proportion of these deposits that remains to be mined, nor the possible or relative advantages to be derived from mining in different sections of the country.

2. The exact relation between cost of mining and value of products can not be determined from the statistics. The Census inquiry was designed to obtain a complete statement of the more important items which make up the cost of mining, but there still remain many items of expense of which it was impossible to obtain a record. For this and other reasons the Census figures throw no light whatever upon the profits of mining, or upon the relative shares of the product which go to capital and labor, respectively. The items of expense which are presented separately in the Census reports are summarized in the following statement:

Value of products		$796,826,417
Cost of supplies and materials	$123,814,967	
Salaries, wages, and contract work	429,658,450	
Miscellaneous expenses	71,771,713	
Total cost		625,245,130
Excess of value of products over total cost		171,581,287

Such a calculation would make it appear that the profit of mining was about $170,000,000, but such a conclusion is unwarranted and improper. The figures take no cognizance of the depreciation of the plant, of expenses incident to the sale of the product, or of interest on capital invested; they ignore the element of loss due to bad debts and the element of risk and speculation incident to marketing the products. The value of the product reported to the Census is the value at the mine or quarry. It was beyond the scope of this investigation to follow the product further. The Bureau of the Census made no inquiry concerning the capital, accounts current, or assets of the mine operators, and it was impossible to determine from the schedules received whether the business had been conducted at a profit or at a loss during the year covered by the report.

3. The average earnings of employees can not be determined from these statistics. The reasons why this is not possible are given on page 95, where the statistics for employees and wages are discussed.

4. The Census figures can not be used to determine the respective shares of capital and of labor in the results of mining operations. The amount of money reported as paid out during the year in the form of wages can be taken as the contribution which the mining operators returned to the wage-earning class from the results of operations carried on, but what relation this sum bears to the interest earned on the total capital invested or to the total profits of mining it is impossible to estimate. Such relations can be determined only by special investigations of typical mines in selected lines of production.

IV.

NUMBER OF MINES, QUARRIES, AND WELLS.

A consideration of primary importance in any census investigation is the selection and proper definition of a suitable unit of enumeration. Generally the unit chosen is one that is sanctioned by common experience, as the individual in the enumeration of the population, the farm in agriculture, the establishment in manufactures, and the mine in mines and mining.

As defined by the mining laws of the United States the word "mine" applies to a single mining claim or a single shaft or other opening, and the term has been used in this sense whenever such a claim was mined separately. In the case of many mining properties, however—particularly those that were at an advanced stage of development—it was found that the property had grown beyond the boundary of one claim and included contiguous claims that frequently were connected with the original claim by underground tunnels and workings, and were so closely associated with it in their operations that even the owner or lessee could not segregate the operations of the different claims. The Bureau of the Census has designated as a mine, any claim or group of contiguous claims operated as a single property. In certain cases, however—as in that of the larger coal companies operating in the anthracite region of Pennsylvania—it was found impracticable to secure separate reports for collieries in the same county, even when noncontiguous, and in such instances, the reports were frequently made on a single schedule. On the other hand, in case of a mine worked by several lessees, each of whom operated independently, separate reports were often made, but whenever possible a single report of the operations was secured from the lessor, or the reports of the several lessees were consolidated. The operation of mines by lessees is a condition frequently found in the mining of precious metals and in the zinc mining region of southwestern Missouri.

A single oil or gas well under individual management or a number of contiguous wells under the same management were considered, for census purposes, as a single mine, but each well was also enumerated and counted in the tables as a separate unit. In the production of some minerals, such as precious stones, placer gold from small placer deposits, and monazite, mining in many instances was not carried on continuously at the same locality, and it was impossible to ascertain the number of distinct mining operations. The term "operator" represents the individual, company, or corporation that controls the mine. The distinct mining operations under the control of the same operator and located in the same county were included in one report to the Bureau of the Census, or in separate reports, to suit the convenience of the operator, but if the distinct operations were situated in different counties a separate report was made for each county.

At the census of 1880 the term "establishment of industry" was used in compiling the statistics of the mining industry. In defining this term it was said that "the term 'establishment of industry,' as used in these tables, may be taken to mean a mining operation the accounts of which are separate, and the product of which is not mingled with that of any other before it is shipped, though at the same time it may consist of numerous distinct mine openings."[1] This definition is in general, consistent with that adopted in this report, but certain important exceptions have been noted.

In the fieldwork of the present investigation special agents were instructed as follows: "It is important that a separate return be made for each mine or quarry, and that the statistics of employees, wages, expenses, and supplies entered on the schedule pertain only to

[1] Tenth Census, Vol. XV, Report on Mining Industries, page xxiv.

the mine or quarry reported. This rule should be observed in all branches of mining and quarrying except petroleum and natural-gas wells, where all the wells located in a certain group or conducted under one ownership should be reported upon the same schedule. However, if more than one mine or quarry in the same county is owned by the same company or firm, and it is impracticable to make a separate report for each, a combined report may be made which will include the operations of all. Mines or quarries, under the same ownership in different counties, must be reported on separate schedules. If a schedule includes the operations of more than one mine or quarry, a memorandum, giving the name and post office address of each mine or quarry included, should be attached to the schedule." Sometimes it was impossible to state the number of mines reporting; this was the case with precious stones which, as a rule, are not obtained from regularly operated mines but through occasional findings or through systematic search. In such cases there is no mine, and the number of operators only is shown. It was also impracticable to ascertain the number of separate mines for gold and silver, and copper, and the number given is the number of operators. This practice was also followed in lead and zinc.

In order to comply with the requirements of the law the canvass covered all mines and quarries, both large and small, and therefore included not only the commercial mines but also those worked to supply a local demand, such as the limestone quarry operated by a farmer to secure material for his own consumption or to furnish lime for the use of the immediate neighborhood, and the small, irregularly worked, bituminous coal mines. This practice has resulted in the inclusion of the large, fully equipped mining plants and the small stone quarries worked at irregular intervals. The large and small mines are given equal weight in ascertaining the number of mines and the number of operators. It is evident, therefore, that the unit, "a mine," is ambiguous and does not always signify the same thing. A thorough enumeration of the small mines or quarries worked to supply a product for local consumption is not essential to a mining census. They are incidental to the canvass, and special effort should be made to enumerate them only when they are characteristic of a locality or mineral. For instance, the enumeration of the small lead miners of Missouri or of the small bituminous coal operators of Kentucky is important, but, as explained on page 18, it is impossible to enumerate all of the small placer gold miners and their omission makes no appreciable difference in the aggregates. This is especially true when the total production of the metal can be obtained from other and more reliable sources.

The increase in the number of mines reported at different censuses is not necessarily an indication of an increase in the mining industry as a whole. The small operators might be especially active during the year of the canvass, while a number of the large mines might be idle or working on part time. Under such conditions the reports would show a larger number of mines but fewer wage-earners, less wages, and a smaller product than would be the case if the conditions were reversed. This is illustrated by the statistics for coal mining. There were 12,552 coal mines reported at the Eleventh Census, with 294,415 wage-earners, and a product valued at $160,226,323. In 1902 the number of mines reported decreased to 5,986, while the number of wage-earners increased to 350,329 and the value of the product, to $367,032,069.

No figures at previous censuses are available for a satisfactory comparison of the number of mines for all minerals, but the following statement shows the number of producing mines reported for some of the most important minerals at the censuses of 1902 and 1889:

Number of producing mines for principal minerals: 1902 and 1889.

MINERAL.	NUMBER OF MINES AND WELLS.	
	1902	1889
Coal, anthracite	334	414
Gold and silver	2,992	3,729
Iron ore	525	592
Natural gas	15,806	2,247
Petroleum	118,671	35,163
Quicksilver	41	11

The number of mines was not shown at the Eleventh Census for many of the most important minerals, such as copper, lead, zinc, and manganese, and it is impossible to determine the number of independent properties engaged at that time in the production of these minerals. The above statement indicates that there were more mines engaged in the production of iron, anthracite coal, and the precious metals in 1889 than there were in 1902, and this is probably true for iron and coal. Notwithstanding this apparent decrease in the number of mines, there has been a large increase in the amount and value of the products for all the minerals enumerated. When, as is frequently the case, more than one variety of mineral is obtained from the same mine, it is impossible to give the number of mines producing each variety, and then present totals, without some duplication. This duplication was avoided at the present census by classifying the reports according to the mineral of chief value and counting each mine as a single unit, irrespective of the number of distinct minerals obtained from it.

The mines reported for each classification have been arranged in three groups: (1) Active mines reporting production; (2) active mines reporting no production, the work being confined to development, exploitation, or care of the property; (3) mines that were idle during the entire year. The number of these different classes of mines reported for each classification of minerals is shown in Table 15.

TABLE 15.—NUMBER OF ACTIVE AND IDLE MINES BY CLASSIFICATION OF MINERALS: 1902.

MINERAL.	Total.	Active mines with production.	Active mines without production.	Idle mines.

Tin	3	.....	.....	3
Tungsten	8	4	.....	4
Uranium and vanadium	5	3	.....	2

There was no attempt to make a complete enumeration of the idle mines and quarries, and the number reported includes only those that were enumerated incidentally in the canvass of the active properties. Many idle mines are virtually abandoned, and an enumeration of them would have no significance. In addition to the 163,580 active and idle mines, quarries, and wells, reports were received from 5,511 unpatented mining claims on which only assessment work was done during the year. Of the 151,516 productive mines, quarries, and wells, 118,671, or 78.3 per cent, were petroleum wells, and only 4,280, or 2.8 per cent, were engaged in the production of ores. The remaining 28,565, or 18.9 per cent, produced fuels; structural, abrasive, and chemical materials; pigments; and miscellaneous substances.

V.

NUMBER OF OPERATORS.

The 151,516 producing mines were controlled by 46,858 operators. The term "operator," as used in this report, stands for the individual, firm, incorporated company, or association that operates the mine or combination of mines. The "operator" is a more definite unit of measurement than the "mine." It represents a distinct interest and conveys an idea of the number of separate properties. It can be applied with some degree of certainty to the employees, wages, and value of products to determine the magnitude of the individual holdings, and such a comparison is made, for the principal minerals, in the following table:

TABLE 16.—AVERAGE NUMBER OF WAGE-EARNERS, WAGES, AND VALUE OF PRODUCTS PER OPERATOR, FOR THE PRINCIPAL MINERALS: 1902.

MINERAL.	Number of operators.	WAGE-EARNERS.		WAGES.		VALUE OF PRODUCTS.	
		Average number.	Average per operator.	Total.	Average per operator.	Total.	Average per operator.
Total	46,858	581,728	12	$369,959,960	$7,895	$796,826,417	$17,005
Coal, anthracite	119	69,691	586	38,716,113	325,345	76,173,586	640,114
Coal, bituminous	4,409	280,638	64	181,482,288	41,162	290,858,483	65,969
Copper ore	144	26,007	181	21,151,405	146,885	51,178,036	355,403
Gold and silver ore	2,992	36,142	12	36,077,492	12,058	82,482,052	27,568
Iron ore	332	38,851	117	21,531,792	64,855	65,465,321	197,185
Lead and zinc ore	557	7,881	14	4,329,271	7,772	14,600,177	26,212
Marble	75	4,070	54	2,212,640	29,502	5,044,182	67,256
Natural gas	1,967	4,678	2	2,936,279	1,493	30,867,863	15,693
Petroleum	29,522	17,552	1	13,242,361	449	71,397,739	2,418
All other minerals	6,741	96,218	14	48,280,319	7,162	108,758,978	16,134

Considering all classes of minerals, each operator gave employment on the average to 12 wage-earners and paid $7,895 in wages during the year, the annual product being valued at $17,005. The production of anthracite coal shows the largest results per operator and the production of petroleum the smallest per operator. While from a statistical standpoint both petroleum and natural gas are properly classed as minerals, the methods of production and distribution differ so radically from those of all other minerals that the statistics are not

comparable and should, as far as possible, be treated separately. Excluding petroleum and natural-gas wells, there were 17,039 mines and quarries, controlled by 15,369 operators. Each operator employed on the average 36 wage-earners, paid $23,019 in wages, and reported a product valued at $45,192. Next to anthracite coal, the largest establishment per operator is shown for copper ore. In this industry 181 wage-earners were employed on the average by each operator.

Large and small operators.—These averages per operator are a general indication of the magnitude of the individual establishments for the entire country, but the large number of small operators included in the total tends to reduce the size of the average establishment without an increase in the total production corresponding to the number of operators employed. For instance, the average operator in anthracite coal gave employment to 586 wage-earners, but returns have been received from one operator in this industry who gave employment to as many as 22,662 wage-earners on the average during the busiest month of the year and who paid more than $6,000,000 in wages for the year's operation, the product being valued at more than $10,700,000. A report was also received from the operator of a copper mine who gave employment to 4,700 wage-earners during the busiest month, paid more than $2,700,000 in wages, and had an annual product valued at more than $8,800,000, whereas the average number of wage-earners employed per operator for this mineral is only 181. In the production of iron ore a single operator reported the employment of 4,664 wage-earners for the busiest month and paid more than $2,600,000 in wages, the value of his annual product amounting to over $11,700,000.

The average operator in the production of precious metals gave employment to only 12 wage-earners during the year, but the operator most largely engaged in the production of these minerals gave employment to 2,029 wage-earners during the busiest month of the year, paid in annual wages over $2,203,851, and had a product valued at the mine at more than $4,300,000.

When petroleum and natural gas are left out of consideration, the largest operator was reported for bituminous coal. This establishment gave employment to 15,629 wage-earners on the average during the year, paid more than $8,800,000 in wages, and had a product amounting to over $13,000,000.

The following table groups the operators according to the values of their products, and thus indicates the proportions of the total product obtained by large and small operators. The reports for petroleum and natural-gas companies have been excluded from this table, and the value of the by-products, referred to on page 25, have been reassigned to the total for the mineral from which they were obtained. This arrangement enables the presentation of the total value of products for each operator.

TABLE 17.—NUMBER OF OPERATORS AND VALUE OF THEIR PRODUCTS, GROUPED BY MINERALS INTO CLASSES BASED ON VALUE OF PRODUCT: 1902.

[Values have been omitted wherever they disclosed the products of individual establishments. Statistics for natural gas and petroleum are not included in this table.]

MINERALS BY GROUPS.	TOTAL.		LESS THAN $500.		$500 BUT LESS THAN $1,000.		$1,000 BUT LESS THAN $10,000.		$10,000 BUT LESS THAN $50,000.

[1] Custom mills which treated "sludge."
[2] Includes for lead and zinc ore the production of 16 custom mills treating "sludge" and the production of numerous small mines reported by landowners, no operators being given; and for gold and silver the production from deep and placer mines reported without operators.

In order to avoid disclosing the affairs of individual operators, the value of products is omitted from a number of the groups shown in Table 17, and for the same reason the statistics are not shown for the separate classifications under "abrasive materials," "chemical materials," "pigments," and "miscellaneous."

The following table, based on Table 17, shows the proportion that the number of operators and the value of their products for the different classes of establishments are of the totals for the United States and for each group of minerals:

TABLE 18.—NUMBER OF OPERATORS, CLASSED BY VALUE OF PRODUCT, WITH PERCENTAGE EACH CLASS IS OF TOTAL: 1902.

[Statistics for natural gas and petroleum are not included in this table.]

[1] Less than one-tenth of 1 per cent.
[2] Includes the production of 16 custom mills treating "sludge;" the production of numerous small mines reported by landowners, no operators being given; and the production of gold and silver ore from small mines for which no operators were reported.

The total for all minerals, exclusive of petroleum and natural gas, shows that 211 operators, or 1.4 per cent of the total number, reported products aggregating $343,819,735, or 49.5 per cent of the total for all mines. Each of these operators reported a product valued at $500,000 or over. On the other hand, 5,494 operators, or 35.7 per cent of the total number, reported a product valued at $1,772,464, or only three-tenths of 1 per cent of the total; each of these operators reported a product valued at less than $1,000. There were 4,764 operators who reported a product valued at $10,000 or more, the total amounting to $673,130,199. They constituted only 31 per cent of the total number of operators, but their products formed 96.9 per cent of the total value of products. In other words, less than one-third of the operators produced more than nine-tenths of the mining products of the country, exclusive of petroleum and natural gas. The concentration of production is more pronounced in some of the minerals than in others. For instance, of the total for metallic substances, 3.9 per cent of the operators produced 72.7 per cent of the product; in coal mining, 5.2 per cent of the operators produced 65.4 per cent of the product; in structural materials, 25.2 per cent of the operators produced 91.3 per cent of the product; in abrasive materials, 18.7 per cent of the operators produced 73.2 per cent of the product; and in the production of all other substances, 29.1 per cent of the operators produced 88.2 per cent of the product. The table shows for each group of minerals a marked decrease in the percentage of operators in the higher value groups, accompanied by a corresponding increase in the proportion which their products formed of the total for all producers.

It has been the practice at previous censuses to omit from the tabulation the reports for all establishments showing an annual product valued at less than $500. If this practice had been followed at the mining census of 1902, there would have been omitted from the total 5,345 operators, or 29.8 per cent of all operators, their product being valued at $916,214, or one-tenth of 1 per cent of the total value of all products. These figures are exclusive of the reported values of product for several small operators connected with the Standard Oil Company, whose products, which were less than $500 each in value, are included in the returns made by that company. The omission, therefore, of the small operators would have but slight effect upon the statistics of production and labor.

The conditions in the mining industry differ radically from those in manufactures. The omission of the establishments with a product of less than $500 is made in the statistics of manufactures so as to avoid the necessity of securing and tabulating returns for small shops in which no one is employed except the owner, who may also be engaged in doing odd jobs, and would thus be more properly classed as a mechanic than as an independent manufacturer. This explanation would not apply to the statistics for mines and quarries. Many mines are operated only a part of the year, and the limited production is due to the short time of operation rather than to the size of the mine or to the extent of the deposits.

As explained on page 20, 7 returns were received from the Standard Oil Company relating to the production of petroleum and 4 relating to the production of natural gas. These schedules covered the work of 28,925 oil operators and 19 gas operators. As only 1 combined report was made for a large number of the operators, it is impossible to segregate the production of the operators so as to assign them to the different groups according to their production. The statistics of natural gas and petroleum are presented in Tables 19 and 20, the Standard Oil Company being considered as a single producer of both natural gas and petroleum.

[1] Exclusive of 28,942 operators whose operations are included in the reports of the Standard Oil Company, which has been classed as a single operator.
[2] Exclusive of 18 operators whose operations are included in the reports of the Standard Oil Company, which has been classed as a single operator.
[3] Exclusive of 28,924 operators whose operations are included in the reports of the Standard Oil Company, which has been classed as a single operator.
[4] Less than one-tenth of 1 per cent.

According to the table on page 60 the production of the average operator in natural gas was valued at $15,693 and in petroleum at $2,418, but in making these calculations the individual operators covered by the reports of the Standard Oil Company were counted as separate units. Considering the report of the Standard Oil Company as that of a single operator, it appears that seven-tenths of 1 per cent of the operators produced 77.5 per cent of the total production of petroleum and natural gas, or 52.7 per cent of the natural gas and 88.2 per cent of the petroleum.

VI.

CHARACTER OF OWNERSHIP.

The operators of mines and quarries were reported to the Census either as (1) individuals; (2) firms and limited partnerships; (3) incorporated companies; and (4) "other forms," embracing cooperative associations, municipalities, penal institutions, etc. The following table shows the number of operators and value of product under each of these classes of ownership as re-

ported for each mineral and group of minerals. In this and the succeeding tables presenting the value of product according to the character of ownership, the value of the by-products referred to on page 25 have been included as a product of the mine or quarry producing them, irrespective of their character. This is necessary in order to show the total production of each operator.

TABLE 21.—NUMBER OF OPERATORS AND VALUE OF PRODUCT, BY CHARACTER OF OWNERSHIP: 1902.

[1] Includes $1,633,835, estimated value of the product of a number of miners working irregularly from whom no reports were received.
[2] Includes $1,965,779, for which character of ownership was not reported.
[3] Standard Oil Company entered as 1 company.
[4] Includes operators as follows: Chrome ore, 1; magnesite, 1; molybdenum, 1; nickel and cobalt, 2; rutile, 1.

Of the 17,318 operators included in Table 21, 8,460, or 48.8 per cent, were individuals; 3,718, or 21.5 per cent, firms and limited partnerships; and 4,951, or 28.6 per cent, incorporated companies; while 189, or 1.1 per cent, were cooperative associations, municipalities, penal institutions, etc.

The number of operators and the value of the production of petroleum are omitted from the table, because the character of ownership was not given for 28,924 of the 29,522 operators reported for the industry. Of the 598 operators of petroleum wells for which the form of ownership was reported, 107 were individuals, 69 firms, 417 incorporated companies, and 5 were reported under various kinds embraced in "other forms." With few and unimportant exceptions, each of the different classes of minerals

enumerated was produced by operators conducting business under all three of the principal forms of ownership; i. e., individual, firm, and incorporated company. Of the 189 operators included in the group of "other forms" of ownership, 78 represent mines, quarries, or wells operated by the United States, or by city, or town governments, or by penal, or eleemosynary institutions. The remaining 111 mines, quarries, or wells were controlled by cooperative associations, receivers, lessees, religious organizations, and other miscellaneous forms of ownership. Of the 6 operators included in the group of "all other minerals," 1 was an individual, 2 were firms, and 3 were incorporated companies.

The following table shows the proportion of the operators and value of products for each mineral and group of minerals produced by individuals, firms and limited partnerships, incorporated companies, and other forms of ownership, respectively:

TABLE 22.—PER CENT DISTRIBUTION, BY CHARACTER OF OWNERSHIP, OF NUMBER OF OPERATORS, AND VALUE OF PRODUCT, FOR EACH MINERAL AND GROUP OF MINERALS: 1902.

[Exclusive of petroleum.]

[1] Less than one-tenth of 1 per cent.

[2] Includes chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile.

Individual ownership.—This form of ownership follows the individual prospector and is peculiar to the development of small mines, large numbers of which were reported for bituminous coal, limestones and dolomites, and for other minerals well distributed and so located that they could be worked with a limited capital. Practically all of the operators in precious stones and the majority of those in natural-gas and petroleum wells were enumerated as individuals. Nearly half of all the mining operations reported were con-

ducted by individuals, and this form of ownership existed in the production of practically all kinds of minerals; but the production itself was comparatively unimportant. This is indicated by the value of product, which amounted to $44,462,756 in the case of individuals, and formed only 6.1 per cent of the total for all mines. Comparatively few individual operators conducted enterprises of great magnitude, but in the production of 13 different classes of minerals, enumerated in Table 21, the product reported for individual operators exceeded that of firms or partnerships. In no case, however, did the value of the products of individuals exceed the value of the products of incorporated companies.

Firms or partnerships.—In many instances these forms of ownership are but a step to the formation of incorporated companies. They include all firms and partnerships, whether general or limited. The 3,718 firms or partnerships formed 21.5 per cent of the total number of operators, and their products were valued at $52,782,143, or 7.3 per cent of the total value of products. The number of firms or partnerships was not as great as the number of individuals, but the value of their products exceeded the value of the products of individuals by $8,319,387, or 18.7 per cent. The product under the firm or partnership form of ownership exceeded the product under incorporated companies in the cases of manganese ore, barytes, and mica. No firms or partnerships were reported as engaged in the production of borax, bauxite, fuller's earth, tungsten, or uranium and vanadium.

Incorporated companies.—From the standpoint of value of products the incorporated form of ownership now predominates in both manufactures and mining, but especially in mining. According to the reports of the census of 1900 the value of the products of incorporated companies engaged in manufactures formed 59.5 per cent of the total gross value of products of all manufactures. In the mining industry the products of the incorporated companies formed 86.3 per cent of the total for all mines and quarries. This form of ownership includes all joint stock companies, the capitalization of which is usually divided into shares of a fixed authorized value, transferable at the option of the individual shareholders. These companies are usually incorporated under the general corporation laws of the different states, but in a number of instances the charters are obtained by a special act of the legislature. The predominating importance of the corporation in the production of the different classes of minerals is shown by Table 22. This form of ownership was reported for all of the minerals, with the exception of buhrstones and millstones, lithium ore, tungsten, and uranium and vanadium, and in all, with the exception of manganese ore, barytes, mica, slate, and "all other minerals," the value of the products of the incorporated companies was far in excess of that shown for the other forms of ownership. In the majority of cases it was more than double the value of products reported for either individuals or firms.

The great increase in the consumption of coal and the demand for raw material to meet the requirements of manufactures has resulted in a general and extensive development of the mining industries, especially those for which the deposits are confined to well-defined geographic districts. Extensive mining operations can be carried on successfully only by the employment of large capital, and the incorporated form of ownership is the most convenient method of raising such capital. Incorporated companies organized primarily for manufacturing enterprises frequently engage in mining in order to control the supply of raw material and to enable themselves to practice economy in production. The production of borax, molybdenum, and rutile was controlled entirely by incorporated companies during the census year.

The incorporated form of ownership in all branches of minerals is of such overwhelming importance that the statistics for employees, salaries, wages, expenses, and products for such companies are of great importance when compared with similar statistics for all other forms of ownership. The following table makes a comparison of this character for each class and for the different groups of minerals:

TABLE 23.—COMPARISON OF STATISTICS FOR INCORPORATED COMPANIES AND FOR ALL OTHER FORMS OF OWNERSHIP, BY MINERALS, AND GROUPS OF MINERALS: 1902.

[Exclusive of petroleum.]

To avoid disclosing the operations of individual establishments it was necessary to combine in Table 23 the statistics for corundum and emery, crystalline quartz, oilstones, whetstones, and scythestones, and asbestos, bauxite, fuller's earth, marl, and monazite.

While the number of incorporated companies (4,951) formed only 28.6 per cent of the total number of operators, they gave employment to 479,618, or 85 per cent of the wage-earners, and paid $306,369,622, or 85.9 per cent of the total wages paid by all operators. These companies also paid $49,707,399, or 88.9 per cent of the miscellaneous expenses, and the cost of their supplies and materials reached $93,115,790, or 87.8 per cent of the total cost, while the value of their products, amounting to $626,132,335, was 86.3 per cent of the value of products for all mines, quarries, and wells.

Incorporated companies have assumed the greatest importance in the production of ores. They employed 98,837, or 89.5 per cent of the wage-earners in the metallic group and paid them $74,888,135, or 89.1 per cent of the wages. The products were valued at $192,297,393, forming 89.3 per cent of the total value of products in this group.

Practically the entire production of copper ore was under the control of incorporated companies, these companies employing 97.9 per cent of the wage-earners and reporting 98.5 per cent of the total value of products for this mineral. Only 144 operators were reported for this mineral and but 44 of them were unincorporated, their product forming only 1.5 per cent of the total value of the product. In the metallic group of minerals iron ore stands next to copper in the part played by incorporated companies, this form of ownership giving employment to 36,316, or 93.5 per cent of the wage-earners and reported products valued at 96.7 per cent of the total value of products for this mineral. The large number of small operators engaged in the production of lead and zinc ore in Missouri and in the production of precious metals throughout the Western states reduced the comparative importance of incorporated companies in the production of these minerals. Manganese ore was the only exception to the predominance of the corporation in the production of ores. The production of this mineral is still largely under the control of individuals and firms.

Next in importance to the ores, in the production by the incorporated form of ownership is the group of minerals classed as fuels. In the foregoing table the statistics for fuels do not include the production of petroleum. Of the 6,477 operators reported for anthracite and bituminous coal mines and natural-gas wells, only 2,226, or 34.4 per cent, were incorporated companies. These companies, however, gave employment to 317,121, or 89.3 per cent, of the 355,007 wage-earners, and their products, valued at $356,399,452, formed 89.6 per cent of the total value of products for this mineral. In this group the predominance of the incorporated form of ownership was especially pronounced in the production of natural gas, the incorporated companies employing 96.7 per cent of the total number of wage-earners, and producing 95.7 per cent of the total products. In the production of anthracite coal, 76 incorporated companies, forming 63.9 per cent of the operators, employed 63,317, or 90.9 per cent, of the wage-earners, and their products, valued at $69,209,224, formed 90.9 per cent of the total value of the products of the industry. The 1,517 incorporated companies engaged in the mining of bituminous coal gave employment to 249,280, or 88.8 per cent, of the wage-earners, and the value of their products, amounting to $257,639,338, formed 88.6 per cent of the total value of bituminous coal mined during the year.

Of the 5,746 operators reported for structural materials, 879, or only 15.3 per cent, were incorporated companies. This comparatively small proportion of incorporated operators controlled considerably more than half of the industry. Their wage-earners, numbering 53,589, formed 62.1 per cent of all wage-earners, and their products, valued at $64,208,623, formed 66.6 per cent of the products. Of the different classes of minerals included in this group the incorporated form of ownership predominated for cement, limestones and dolomites, and marble. The manufacture of cement reported by the Census was confined to establishments operating quarries. Practically the entire output obtained in this manner was produced by incorporated companies. These companies gave employment to 98.6 per cent of the wage-earners engaged in the industry, and their production formed 99.3 per cent of the value of the products. Only 10 of the 93 operators were unincorporated, and their production formed only seven-tenths of 1 per cent of the total value of the product for the industry.

The incorporated companies engaged in the production of limestones and dolomites gave employment to 59.5 per cent of the wage-earners reported for all quarries devoted to the production of these stones, and in value their products formed 59.8 per cent of the total. A greater preponderance of the incorporated form of ownership is shown for marble, the incorporated companies in this industry employing 87.1 per cent of the wage-earners, and reporting 88.6 per cent of the total value of products.

The production of clay reported by the Bureau of the Census was confined to the products sold as such, and did not include the manufacture of brick and pottery products. While the number of wage-earners and the value of the product reported for the unincorporated operators engaged in clay mining and in the quarrying of sandstones and quartzites, siliceous crystalline rocks, and slate, were slightly in excess of those reported for incorporated companies, the indica-

tions are that the incorporated form of ownership is assuming control of these industries.

The mines engaged in the production of abrasive materials and controlled by incorporated companies gave employment to 60.5 per cent of the wage-earners reported for this group, and their products formed 75.6 per cent of the total value. Only 29 quarries were reported as engaged in the production of buhrstones and millstones as their principal products. Twenty-three of these quarries were operated under the individual form of ownership and 6 by firms or partnerships. The larger proportion of buhrstones and millstones was obtained from sandstone quarries, which are included under the group of structural materials. The figures in Table 23, therefore, do not indicate the proportion of the products of this class obtained from quarries operated by incorporated companies. The incorporated form of ownership predominated in all of the other minerals included in the group of abrasive materials with the exception of garnet. In the case of garnet 3 of the 7 operators were incorporated, and they reported a product valued at $27,900, or 21 per cent of the total for this mineral.

The production of chemical materials shows a decided preponderance in favor of the incorporated form of ownership, over 78 per cent of the production of each mineral being reported by incorporated companies. Taking this group as a whole, the corporations—116 out of the 174 producers—employed 84.7 per cent of the wage-earners, paid 85.2 per cent of the wages, and reported 88.3 per cent of the total value of the product.

Of the 77 producers of pigments, 28 were incorporated. These incorporated companies employed 286, or 48.3 per cent, of the 592 wage-earners, and paid $109,480, or 46.3 per cent, of the wages, and their products amounted to $371,651, or 65.9 per cent, of the total for the group.

The miscellaneous group of minerals, taken as a whole, shows that the business of incorporated operators predominated in the proportion of about 3 to 1. They constituted 15.1 per cent of the 688 producers, employed 79.5 per cent of the 2,433 wage-earners, paid 78.6 per cent of the $1,035,784 paid in wages, and reported a product valued at $2,592,192, or 77.5 per cent, of the total for the group.

Petroleum.—As previously explained, the character of ownership was not reported for 28,924 operators engaged in the production of petroleum, and for this reason the data were excluded from the preceding tables. In the following table the report for the Standard Oil Company has been considered as that of an incorporated company covering the operations of 28,924 other operators. While this rearrangement does not show the true character of the ownership of the individual operators, it probably conveys an accurate idea of the actual control of the production.

TABLE 24.—*Summary for petroleum for incorporated and unincorporated operators: 1902.*

	Total.	Incorporated companies.	Per cent of total.	Unincorporated operators.	Per cent of total.
Number of wells	118,671	116,307	98.0	2,364	2.0
Number of operators	598	414	69.2	184	30.8
Salaried officials, clerks, etc.:					
Number	3,033	2,323	76.6	710	23.4
Salaries	$2,986,768	$2,927,423	98.0	$59,345	2.0
Wage-earners:					
Average number	17,552	17,350	98.8	202	1.2
Wages	$13,242,361	$13,045,370	98.5	$196,991	1.5
Contract work	$12,956,631	$12,465,386	96.2	$491,245	3.8
Miscellaneous expenses	$15,811,726	$15,651,684	99.0	$160,042	1.0
Cost of supplies and materials	$17,781,512	$17,398,757	97.8	$382,755	2.2
Value of product	$71,397,739	$69,920,060	97.9	$1,477,679	2.1

The operators included as incorporated companies in the above table and engaged in the production of petroleum gave employment to 17,350, or 98.8 per cent, of the wage-earners, and their wages amounted to $13,045,370, or 98.5 per cent, of the total wages paid in the industry. Their products were valued at $69,920,060, or 97.9 per cent, of the total value of product.

Industrial combinations.—The statistics presented in the preceding section indicate the extent to which the firm and the incorporated company have assumed control of the mining industries. The exigencies of production on a large scale and the desirability of controlling all or a large portion of the deposits of certain minerals, combined with the advantages of carrying on mining and manufacturing under the same management and with the use of the same capital, have led to the consolidation of formerly independent operators and the formation of what are commonly known as industrial combinations. Such combinations are a form of incorporated ownership, and the statistics for them should be considered in connection with those for incorporated companies. This form of ownership has assumed large proportions in the manufacturing industries. In presenting the statistics of combinations in these industries the following definition was given in the report of the Twelfth Census on manufactures:

> For the purpose of the Census the rule has been adopted to consider no aggregation of mills an industrial combination unless it consists of a number of formerly independent mills which have been brought together into one company under a charter obtained for that purpose. We therefore exclude from this category many large establishments comprising a number of mills which have grown up, not by combination with other mills, but by the erection of new plants or the purchase of old ones.
>
> The word "trust" was avoided in this definition, because, while it may have come to convey to the popular mind a definite idea, it stands technically for a form of organization under which the stockholders of each of the separate companies assign their stock to a certain number of trustees, thus giving to these trustees an irrevocable power of attorney to vote the stock as they see fit. This form of organization has been declared illegal by the act of July 2, 1890, Fifty-first Congress, first session, entitled "An act to protect trade and commerce against unlawful restraint of monopolies" (26 Statutes at Large, page 209), and by the statutes of many states.

While the compilation of statistics for manufactures in conformity with this definition resulted in the presentation of totals which show the extent to which formerly independent establishments have come under the same ownership, and the magnitude of their operations, they do not show the extent to which the production has become concentrated in fewer establishments. In order to show such concentration it is necessary to consider all large establishments, irrespective of the method of their formation, and this has been done for the mining industries in Sections V and VI of Chapter II. As the extent of the deposits of many minerals can be determined very accurately and the production controlled through their purchase, the mining industries hold out inducements which do not exist in other industries to the formation of industrial combinations or other forms of business organizations to control the production.

The operations of a number of corporations in the mining industry have acquired enormous proportions through the gradual purchase and development of new properties, and there are numerous cases of consolidation of small independent operators, especially in the production of gold, silver, lead, and zinc. While the object of these consolidations may sometimes be the reduction of operating expenses, such consolidations are frequently made with the intention of issuing a larger amount of capital stock than was possible under an independent form of organization. In many instances independent mining claims or prospects have been made the basis for the organization of corporations, and the claims have been capitalized on their possible production, although mining operations had not actually commenced at the time of the formation of the company.

The production of some minerals is probably controlled by a mutual understanding between the operators of the mines or between the operators and transportation companies, but it is impracticable to identify operations which are controlled by arrangements of this character.

A number of the companies included in the mining census were engaged in other industries, such as manufacturing or transportation; the mining operations were incidental to their other interests, and it was impossible to segregate the capitalization so as to assign a proper proportion to the mining interests. The Standard Oil Company, for example, is engaged primarily in the refining of petroleum and produces only a limited amount of crude material; but, as explained on page 20, this company made reports covering the operations of a large number of producers of petroleum. The United States Steel Corporation is engaged primarily in the manufacture of iron and steel products, but it also operates a number of iron ore and coal mines, limestone quarries, and natural gas wells, and its capitalization covers other interests. A number of large companies which are engaged extensively in manufacturing, as well as in mining and other industries, have reported their entire capitalization in reply to the inquiries on the mining schedule, together with all dividends and interest accrued from the profits of both the mining and manufacturing operations, declaring that it was impossible to make a separation. Notable among such companies are the Republic Iron and Steel Company, the Sloss-Sheffield Steel and Iron Company, the New Jersey Zinc Company, the Alabama Consolidated Coal and Iron Company, the Colorado Fuel and Iron Company, the Empire Steel and Iron Company, the Pacific Coast Company, the Philadelphia Company, the Tennessee Coal, Iron, and Railroad Company, and the Virginia Iron, Coal, and Coke Company. This is also true, to a greater or less degree, of most of the companies reporting capital stock, as a very small proportion of them confine their operations solely to mining.

It is evident, therefore, that while industrial combinations similar to those referred to in the report on manufactures of the Twelfth Census do exist in the mining industries, it is impracticable to compile satisfactory statistics for them. But eliminating from consideration the production of coal, petroleum, and natural gas, and compiling the statistics of the rest of the minerals in as close conformity as possible with the definition given above, it is found that industrial combinations exist in the production of several minerals. Table 25 shows for all the items discussed in this chapter the totals for all operators and for industrial combinations in the same minerals and the percentages that the industrial combinations are of the totals for all operators.

TABLE 25.—SUMMARY FOR MINERALS FOR WHICH INDUSTRIAL COMBINATIONS ARE REPORTED: 1902.

	Iron ore.	Copper ore.	Cement.	Limestones and dolomites.	All other minerals.[1]
Number of mines, quarries, and wells:					
Total	525	144	101	3,246	2,904
Industrial combinations	118	21	17	46	72
Per cent of total	22.5	14.6	16.8	1.4	2.5
Salaried officials, clerks, etc.:					
Number—					
Total	2,405	1,208	913	2,231	3,550
Industrial combinations	1,425	443	118	134	264
Per cent of total	59.3	36.7	12.9	6.0	7.4
Salaries—					
Total	$2,113,230	$1,768,456	$1,087,514	$1,843,747	$3,204,259
Industrial combinations	$1,254,657	$644,688	$191,312	$133,171	$333,169
Per cent of total	59.4	36.5	17.6	7.2	10.4
Wage-earners:					
Average number—					
Total	38,851	26,007	13,041	31,547	39,906
Industrial combinations	19,148	11,318	4,319	2,596	2,820
Per cent of total	49.3	43.5	33.1	8.2	7.1
Wages—					
Total	$21,531,792	$21,151,405	$6,328,852	$14,750,638	$22,843,684
Industrial combinations	$11,154,462	$9,787,476	$2,056,750	$1,113,299	$1,443,773
Per cent of total	51.8	46.3	32.5	7.5	6.3
Contract work:					
Total	$425,292	$188,768	$10,627	$36,381	$119,573
Industrial combinations	$148,726	$39,675			$2,000
Per cent of total	35.0	21.0			1.7
Miscellaneous expenses:					
Total	$8,257,714	$1,397,465	$1,665,520	$1,440,081	$4,113,410
Industrial combinations	$5,357,709	$445,344	$558,174	$59,859	$603,011
Per cent of total	64.9	31.9	33.5	4.2	14.7
Cost of supplies and materials:					
Total	$9,005,608	$11,083,175	$9,098,226	$5,403,912	$6,857,657
Industrial combinations	$4,832,372	$4,649,168	$3,461,249	$308,870	$669,528
Per cent of total	53.7	41.9	38.0	5.7	9.8
Value of product:					
Total	$65,465,321	$51,178,036	$24,268,338	$30,441,801	$47,809,532
Industrial combinations	$38,172,009	$28,502,848	$8,189,118	$2,091,225	$3,922,648
Per cent of total	58.3	55.7	33.7	6.9	8.2

[1] Includes asphaltum and bituminous rock, corundum and emery, grindstones and pulpstones, gypsum, lead and zinc ore, oilstones, whetstones, and scythestones, sandstones and quartzites, siliceous crystalline rocks, and talc and soapstone.

The operators classed as industrial combinations and engaged in the production of iron ore gave employment to 49.3 per cent of the wage-earners and in value their products formed 58.3 per cent of the total value of all the iron ore produced during the year. While only 14.6 per cent of the operators of copper mines were classed as industrial combinations, they gave employment to 43.5 per cent of the wage-earners and their products formed 55.7 per cent of the total value of products.

VII.

CAPITAL.

Reasons for not securing statistics.—It has been the practice at prior censuses to include in the report on mining industries statistics concerning capital invested. The object was to ascertain the value of all mining properties and money invested or used in the business, whether owned or borrowed. In order to develop these amounts the inquiries called for the value of the mine and improvements, including land, buildings, fixtures, tools, implements, live stock, machinery, etc., and were in harmony with those concerning capital included in the schedule for the manufacturing and mechanical industries, but the statistics for both branches of industry have frequently been referred to as untrustworthy and delusive. It is evident from the various inquiries made at the Eleventh Census[1] that uniform amounts were not reported for capital invested in all branches of the mining industry, and the statistics can not be accepted as representing the actual value of the mining properties or the amount of capital invested in the industry.

All of the objections to the statistics for capital in manufactures apply with greater force to the statistics for mines and quarries, and they may be summarized as follows:

1. It is impossible to define the word "capital" for statistical measurement so that it shall be tangible, restricted, and uniform.

2. The inquiry creates more prejudice and arouses more opposition to the progress of the enumeration than all of the other inquiries united.

3. The value of "fixed capital"—land and buildings—is dependent upon conditions of which a census can take no cognizance.

4. The difficulties attending the collection of statistics for live capital—"cash on hand, bills receivable, unsettled accounts, etc."—preclude the possibility of reliable results.

5. It is impossible to eliminate the duplication in gross assets and credit capital.

6. Good will, patents, mining rights, etc., are forms of capital for which no satisfactory value can be obtained.

7. Many mining companies have investments other than of the amounts required to carry on their business

[1] The following indicates the character of the inquiries used at the Eleventh Census: For minor minerals the inquiries called for "total value of mine and improvements, as at present developed, distributed as follows: Land; buildings and fixtures; tools, implements, live stock, machinery, and supplies on hand; cash not reported in the foregoing items." The instructions required that the amount of capital should be stated so as to include not only the amount of capital actually invested in the business, as in land, leases, mineral rights, rights of way, private railroads, buildings, tools, and all other forms of property, but also that used in carry-

and yet constituting a part of their capital, such as railroads, steamships, and timber lands, and it is impossible to segregate the capital that pertains strictly to mining.

8. A number of mines are operated under leases. The lessees furnish the Census reports, but have no knowledge of the value of the mine or the capital invested by the lessor in land, shafts, machinery, etc.

9. The value of a mine is due chiefly to the character and amount of ore supposed to be in the earth, and is, therefore, largely speculative.

The act of Congress of March 3, 1899, was the first census law that specified the character of the inquiries to be embraced in the schedule for manufactures, and the "amount of capital invested" formed one of these inquiries. The same law provided for the census of mines, mining, and minerals, but in enumerating the different subjects to be included in the report, no reference was made to the capital invested. The absence of a definite provision of law and the unsatisfactory character of the statistics concerning capital collected at prior censuses, justified the omission of this inquiry from the mining census of 1902. The report for this census, therefore, contains no information concerning the value of the mining property or the actual amount of capital invested in the industry.

Capitalization of incorporated companies, by minerals.—Exclusive of the products of natural-gas and petroleum wells, 85.9 per cent of the mining products of the country during 1902 was produced by incorporated companies, and the prevalence of this form of ownership indicates the desirability of collecting statistics concerning their capitalization. While the capitalization of incorporated companies is not the true value of mining properties, nevertheless, the companies are in position to give the amount of capital stock and bonded indebtedness, and inquiries concerning such values can be answered readily. The census schedule, therefore, contained the following inquiries:

2. Capital stock, bonds, dividends, and assessments (if an incorporated company):

	BONDS.		PREFERRED STOCK.		COMMON STOCK.	
	Number.	Total par value.	Number of shares.	Total par value.	Number of shares.	Total par value.
Authorized		$		$		$
Issued to the end of the year		$		$		$

Dividends and interest, if any, paid during the year:

Common stock, rate ; amount, $

Preferred stock, rate ; amount, $

Bonds, rate ; amount, $

Assessments: Total amount levied, if any, since organization of company $

In the majority of cases the capitalization given in answer to this inquiry included values incident to the operation of all enterprises, industrial and commercial, carried on by the company reporting. For instance, if an iron company owned and operated a coal and an iron mine, the probabilities are that its total capitalization was reported, it being impossible to segregate the amount represented by each mining operation. It is probable that mining was the primary object of the formation of the majority of the companies, but in some cases mining was subservient to other interests, and, in a few instances, where the mining formed only a small proportion of the interests of the corporation, no capital stock was reported. The Pittsburg Plate Glass Company and the American Sewer Pipe Company are corporations of this character. The totals, therefore, can not be accepted as the capitalization of mining enterprises exclusively, nor can the dividends paid be accepted as the result of mining operations only.

Exclusive of those engaged in the production of natural gas and petroleum, there were 4,318 incorporated companies reported as engaged in the mining industries. Of this number, 4,045 answered the

ing on the business. This statement, to be complete, should include as capital "all money borrowed, as well as accounts having a long time to run. The idea is to get returned as capital all money invested and used in the business, whether owned by the party making the return, or borrowed. The value of land, fixtures, etc., should be estimated at what they are worth or would cost in 1890." The inquiry for the precious metals called for separate amounts, as follows: Total present actual cash value of mine and mining plant, $———, to be distributed as follows: Present actual cash value of buildings at mine, $———; present actual cash value of railroads on surface, $———; present actual cash value of machinery of all kinds above and below ground, including pumps, engines, boilers, cars, tools, etc., $———; present actual cash value of underground improvements, including shafts, tunnels, drifts, tramways, etc., $———; present actual cash value of mine supplies of all kinds on hand December 31, 1889, $———; present actual cash value of the mine itself, exclusive of the above items, $———; cash not reported in the foregoing items, $———; value of mill, smelting, or other reduction works, exclusive of mining property; present actual cash value of buildings, $———; present actual cash value of machinery and plant of all kinds except buildings, $———; present actual cash value of supplies on hand December 31, 1889, $———. In addition to these inquiries a circular letter issued to the enumerators on May 26, 1890, instructed them that the total actual value of the entire mining plant at the close of 1889 should be given without regard to the capitalization of the corporation or firm. If the land was owned in fee or in mineral rights, the number of acres attached to the collieries and under development, together with its actual value, should be stated. In the case of leased land, it should be practicable for the lessee to give the value per acre of the tract under development, and an effort should be made by the enumerator to obtain this data either from the lessee, lessor, or other reliable authority. If several collieries were drawing coal from the same bank, the value of the acreage for the same tract should be treated on one schedule and omitted from the others.

inquiries concerning capitalization. A large proportion of the production of petroleum in Pennsylvania, New York, Ohio, Indiana, and West Virginia, and also a considerable amount of the natural gas produced in these states, was covered in the report of the Standard Oil Company. In answering these inquiries this company gave an estimate of the capital stock and bonds it considered devoted to production, eliminating, as far as possible, the stock incident to the refining and to enterprises not directly connected with production of crude petroleum. The company also reported its inability to give the number of incorporated companies whose production of petroleum bought by it was included in its schedules; therefore the number of incorporated companies given in Table 26 for petroleum can not be accepted as the actual number engaged in its production. This table presents the statistics of capitalization for all incorporated companies for each mineral and group of minerals.

TABLE 26.—CAPITALIZATION OF INCORPORATED COM-

	MINERALS, BY GROUPS.	Number of incorporated companies.	Number of companies reporting.	Aggregate par value of stocks and bonds issued.	CAPITAL STOCK. Total.		
					Authorized.	Issued.	Dividends.

Considering the total for the United States as shown by Table 26, it appears that of the 5,386 incorporated companies operating producing mines, 510 failed to answer the inquiry concerning capitalization. The data furnished by the 4,876 companies show that they were authorized to issue stock and bonds to the amount of $3,801,264,332. This total is composed of 1,234,500,357 shares of common and preferred stock, having a total par value of $3,440,194,687, and of bonds to the value of $361,069,645. The capital stock constituted 90.5 per cent of the total authorized capitalization and is composed of preferred stock to the value of $215,957,057 and common stock to the value of $3,224,237,630, the two forms of stock constituting 6.3 and 93.7 per cent, respectively, of the total. Of the total authorized capital stock, $2,902,835,544, or 84.4 per cent, had been issued and was outstanding at the end of the year. The par value of the common stock issued amounted to $2,718,796,984, or 84.3 per cent of such stock authorized, and the par value of the preferred stock issued amounted to $184,038,560, or 85.2 per cent of the total authorized. The par value of the bonds formed 9.5 per cent of the authorized capitalization and the par value of the bonds issued amounted to $314,883,914, or 9.8 per cent of the total capital stock and bonds issued.

Of the $72,416,913 reported as paid in dividends, $63,610,969 was paid on common stock and $8,805,944 on preferred stock, representing an average rate of 2.3 and 4.8 per cent, respectively, on all such stock issued. The interest paid on bonds amounted to $13,603,924, or 4.3 per cent on the par value of the $314,883,914 reported as issued. These percentages of dividends and interest are computed on the total amount of stock and bonds issued, irrespective of whether dividends or interest were paid by every particular corporation, and therefore the percentage of dividends is a total return on the total outstanding capitalization of the mining corporations.

Dividend paying companies.—Exclusive of natural gas and petroleum, 1,142 corporations reported the payment of dividends on common or preferred stock, or interest on bonds during the year, and the statistics for the capitalization of these companies are presented in Table 27 for each mineral.

TABLE 27.—CAPITALIZATION OF INCORPORATED COMPANIES PAYING EITHER

The par value of the authorized capital stock and bonds of the 1,142 companies paying either dividends or interest on all or part of their capitalization amounted to $1,751,116,693, or 46.1 per cent of the total authorized capitalization of all companies reported. The par value of the capital stock and bonds issued by these companies amounted to $1,524,662,218, or 47.4 per cent of the total amount issued by all companies. The capital stock and bonds actually issued by companies paying either dividends or interest formed 87.1 per cent of their total authorized capitalization, and the dividends and interest paid by them represented a return of 4.5 per cent on capital stock and bonds actually issued.

Table 28 shows the amount and kind of capital stock of all companies paying dividends on common or preferred stock.

TABLE 28.—CAPITAL STOCK OF INCORPORATED COMPANIES PAYING DIVIDENDS ON COMMON OR PREFERRED STOCK, BY MINERALS: 1902.

[Exclusive of natural gas and petroleum.]

There were 919 companies that reported the payment of dividends on either common or preferred stock. The par value of the authorized capital stock of these companies amounted to $1,218,990,475, or 35.4 per cent of the total authorized capital stock of all companies, and the par value of the stock issued amounted to $1,045,760,265, or 36.0 per cent of the total capital stock issued by all companies. The dividends which were paid on either or both of these classes of stocks amounted to $56,700,943, or a return of 5.4 per cent on the stock issued by such companies.

Common stock.—Exclusive of the companies engaged in the production of natural gas and petroleum there were 3,724 companies authorized to issue common stock to the amount of $2,721,510,955. Of this number 3,686 companies had actually issued common stock to the par value of $2,306,374,172. As shown by Table 27 the par value of the authorized common stock of companies paying either dividends on one or the other class of stock or interest on bonds amounted to $1,286,510,908, and the par value of the common stock issued by these companies amounted to $1,109,335,428; the dividends paid amounted to $47,972,272, a return of 4.3 per cent on the common stock issued. These amounts include common stock on which no dividends were paid, but which was issued by companies paying dividends on preferred stock or interest on bonds. There were 837 companies that reported the payment of dividends on common stock and the statistics for the common stock of these companies are summarized in Table 29.

TABLE 29.—*Common stock of incorporated companies paying dividends on such stock: 1902.*

[Exclusive of natural gas and petroleum.]

The 60 companies that paid dividends on preferred stock but no dividends on common stock had common stock issued to the value of $183,139,447, or 64.8 per cent of the total common and preferred stock issued by these companies. The dividends paid on the preferred stock of these companies amounted to $6,102,385, a return of 6.1 per cent on the par value of such stock issued.

The common stock issued and on which dividends were paid amounted to $687,810,418, or only 29.8 per cent of the total amount of common stock issued by all companies. The dividends paid on this stock amounted to $47,972,272, or a return of 7 per cent. Of the 3,686 companies reporting the issue of common stock there were 2,849 that paid no dividends on such stock. The par value of the authorized common stock of these companies amounted to $1,920,076,305, or 70.6 per cent of the total for all companies, and the amount issued was valued at $1,618,563,754, or 70.2 per cent of the total amount issued. In addition 60 companies that reported the issue of common stock paid dividends on preferred stock but no dividends on common stock, and the statistics for these companies are summarized in the following table:

TABLE 30.—CAPITALIZATION OF INCORPORATED COMPANIES PAYING DIVIDENDS ON PREFERRED STOCK BUT NOT ON COMMON STOCK: 1902.

Preferred stock.—Exclusive of natural gas and petroleum, there were 244 companies authorized to issue preferred stock to the value of $210,378,437. Of this number 234 companies had actually issued preferred stock to the value of $180,083,899. As shown by Table 27, the par value of the authorized preferred stock of companies paying either dividends on one class of stock or interest on bonds amounted to $168,328,367, and the par value of the preferred stock issued by these companies amounted to $151,003,709. The dividends paid amounted to $8,728,671, or a return of 5.8 per cent on the preferred stock issued. These amounts include preferred stock on which no dividends were paid but which was issued by companies paying dividends on common stock or interest on bonds. There were 87 companies that reported the payment of dividends on preferred stock, and the statistics for the preferred stock of these companies are summarized in the following table:

TABLE 31.—*Preferred stock of incorporated companies paying dividends on such stock, by minerals: 1902.*

[Exclusive of natural gas and petroleum.]

MINERAL.	Number of companies paying dividends.	PREFERRED STOCK.		DIVIDENDS.	
		Authorized.	Issued.	Amount.	Rate per cent.
Total	87	$157,450,867	$140,892,300	$8,728,671	6.2
Cement	7	3,730,000	3,605,000	251,300	7.0

Sandstones and quartzites	1	25,000	20,600	1,224	5.9
Slate	2	400,000	342,000	28,475	8.3
Talc and soapstone	1	2,000,000	1,482,500	59,300	4.0

The preferred stock on which dividends were paid amounted to $140,892,300, or 78.2 per cent of the total amount of preferred stock issued by all companies. The dividends paid on this stock amounted to $8,728,671, a return of 6.2 per cent on the amount issued. Of the 234 companies reporting the issue of preferred stock, there were 147 that paid no dividends on such stock. The par value of the authorized preferred stock of these companies was $52,927,570, or 25.3 per cent of the total for all companies, and the amount issued $39,191,599, or 21.8 per cent.

Bonds.—The $288,720,791 shown as the par value of the bonds issued includes all bonds issued by all companies irrespective of the payment of interest or dividends. The following table presents the statistics for the 363 companies that paid interest on bonds:

TABLE 32.—*Bonds of incorporated companies paying interest on bonds, by minerals: 1902.*

[Exclusive of natural gas and petroleum.]

MINERAL.	Number of incorporated companies.	Bonds authorized.	Bonds issued.	INTEREST.	
				Amount.	Rate per cent.

The bonds issued on which interest was paid amounted to $257,233,551, or 89.1 per cent of the total amount of bonds issued by all companies. The interest paid on these bonds amounted to $12,265,189, or a return of 4.8 per cent on the amount issued. The 363 companies that reported the payment of interest on bonds were authorized to issue bonds to the value of $281,115,418. The amount actually issued and on which interest was paid formed 91.5 per cent of the total authorized bonded debt.

Natural gas and petroleum.—As explained on page 76, the capitalization reported for natural gas and petroleum should be considered separately from that of other minerals. Table 33 shows that the total authorized capitalization of the companies engaged in the production of these substances amounted to $540,723,162, of which $442,540,596 had been issued. This includes the capitalization reported by the Standard Oil Company. A total of $17,054,705 is reported as having been paid in dividends and interest on bonds, representing a return of 3.8 per cent on the capitalization (stock and bonds) issued. In Table 33 the capitalization shown as issued includes all stock and bonds irrespective of the payment of dividends and interest.

TABLE 33.—*Capitalization of incorporated companies producing natural gas and petroleum and reporting capitalization: 1902.*

	Total.	Natural gas.	Petroleum.
Number of companies reporting	831	433	[1]398
Total capital stock and bonds:			
Authorized	$540,723,162	$120,043,673	$420,679,489

Issued	26,163,123	19,443,867	6,719,256
Interest	1,338,735	1,041,402	297,333

[1] The 28,925 producers reported by the Standard Oil Company are included as 1 incorporated company.

Considering the report of the Standard Oil Company as representing a single producer for natural gas and for petroleum, the following table shows the number of operators and the capitalization of the companies reporting the payment of dividends on either common or preferred stock or interest on bonds:

TABLE 34.—*Capitalization of natural gas and petroleum companies paying dividends or interest on bonds: 1902.*

	Total.	Natural gas.	Petroleum.
Number of companies reporting dividends or interest	248	164	84
Total capital stock and bonds:			
Authorized	$323,419,247	$98,013,747	$225,405,500
Issued	$281,335,689	$94,272,929	$187,062,760
Capital stock—			
Authorized	$292,728,380	$78,072,880	$214,655,500
Issued	$256,612,860	$75,446,062	$181,166,798
Common—			
Authorized	$289,528,380	$77,272,880	$212,255,500
Issued	$253,726,423	$74,676,062	$179,050,361
Dividends paid	$15,638,697	$4,894,134	$10,744,563
Rate per cent	6.2	6.6	6.0
Preferred—			
Authorized	$3,200,000	$800,000	$2,400,000
Issued	$2,886,437	$770,000	$2,116,437
Dividends paid	$77,273	$49,900	$27,373
Rate per cent	2.7	6.5	1.3
Bonds—			
Authorized	$30,690,867	$19,940,867	$10,750,000
Issued	$24,722,829	$18,826,867	$5,895,962
Interest paid	$1,338,735	$1,041,402	$297,333
Rate per cent	5.4	5.5	5.0

The par value of the authorized capital stock and bonds of the 248 companies paying either dividends or interest on all or part of their capitalization amounted to $323,419,247, or 59.8 per cent of the total authorized capitalization of all companies reported as engaged in the production of natural gas and petroleum. The par value of the capital stock and bonds issued by these companies amounted to $281,335,689, or 63.6 per cent of the total amount issued. The capitalization actually issued by companies paying either dividends or interest formed 87 per cent of their total authorized capitalization, and the dividends and interest paid by them represented a return of 6.1 per cent on capital stock and bonds actually issued.

Of the 248 companies there were 216 that reported the payment of dividends on either common or preferred stock. The par value of the authorized capital stock of these companies amounted to $225,767,930, or 41.8 per cent of the total authorized capital stock of all companies; and the par value of the stock issued amounted to $211,774,741, or 47.9 per cent of the total capital stock issued by all companies. The dividends that were paid on either or both of these classes of stock amounted to $15,715,970, or a return of 7.4 per cent on the stock issued by such companies.

Capitalization of incorporated companies, by states and territories.—As previously explained, the capital stock of incorporated companies represented their entire capitalization. In some cases the companies operated mines in different states and were engaged in the production of different minerals. For instance, a mining company engaged primarily in the production of iron ore may also operate a limestone quarry, and some of its enterprises may be located in different states. It was impracticable to segregate the capital stock so as to show the amount devoted to each industry in each state, therefore the total capitalization was assigned to the mineral or state representing the interest of greatest value. With the exception of buhrstones and millstones, lithium ore, tungsten, and uranium and vanadium, the production of all of the minerals for which separate statistics are shown was controlled to some extent by the corporate form of organization and incorporated companies were reported for every state and territory in which minerals were mined. Statistics concerning employees, wages, expenses, and production of incorporated companies are given in Table 23, page 68, but since in an unknown number of instances the capital stock represented interests other than mining and since the capitalization for some companies was not reported or, for the reasons explained above, was excluded from the statistics, a satisfactory comparison of capitalization and production is impracticable. The statistics for the capitalization for all minerals in each state and territory are presented in Table 35.

TABLE 35.—CAPITALIZATION OF INCORPORATED

	STATE OR TERRITORY.	Number of incorporated companies.	Number reporting.	AGGREGATE CAPITALIZATION.			CAPITAL STOCK.

VIII.

EMPLOYEES AND WAGES.[1]

The schedules used at the Twelfth Census for collecting statistics of employees and wages contained several important inquiries not used at previous censuses. Thus in 1902 employees were segregated into general groups of occupations, to show the prevailing daily rates of pay for each occupation and the average number employed during each month of the year; the number engaged in mining or quarrying who received pay according to the quantity of work done (namely, the number of tons, cars, or yards mined) and the total amount paid for such work; the amount paid for contract work, such as tunneling, sinking of shafts, boring test holes, etc., when done by independent contractors, and the number of men employed in such work; and, finally, the total number of days that the mines or quarries were in operation during the year.

No provision was made in the schedule for a separate report of female employees, either wage-earners or those receiving salaries. There is no doubt that among the salaried employees there were some female clerks, but so few as to be a negligible quantity and of no statistical importance, and none of them was engaged in the actual mining or quarrying. On the other hand the number of females engaged in the different branches of manufacturing is comparatively large and, therefore, of vital economic and sociologic importance.

In the various tables in this report showing wage-earners and wages comparisons have been made with the statistics of earlier censuses whenever they were available; but because of the adoption of a radically different method of ascertaining the average number of wage-earners at this census any comparisons will be invalidated to a considerable degree. In the schedules for 1889 the inquiry as to the number of persons employed asked for the number of foremen or overseers separately, but the inquiry as to the amount of wages paid did not call for a separate statement as to the amount paid in wages to this class of employees. As a result, the statistics for labor and wages published in the Report on Mineral Industries at the Eleventh Census show separately the number of foremen and overseers, but not the amounts received by them, and in no case can the wages paid to this class of employees be separated. In the statistics for 1902, on the other hand, foremen and overseers, with their salaries, are included with superintendents, managers, surveyors, etc., and not with wage-earners.

Again, the schedule for 1889 called for a separate statement as to the amount paid for contract work, but not for the number of persons employed on such work, though such employees were probably included in the total average number of wage-earners.

In the schedule for 1889 the inquiry as to labor and wages is followed by this note: "In giving the number of men employed include those employed by contractors and subcontractors as well as by the company itself." In the corresponding inquiry of the schedule for 1902 the note of instruction reads as follows: "Amounts paid for contract work not done by employees hired directly, and the number employed in such work, must not be included in this inquiry, but should be reported in answer to inquiry 6." In inquiry 6 of the schedule for 1902 the amount paid for tunneling, shaft sinking, boring test holes, etc., if not done by employees hired directly, and the average number of men employed on such work are asked for separately.

The greatest difference, however, between the statistics for the two censuses results from a radical change in the method of obtaining the average number of persons employed. In editing the schedules for 1902 the figures for the average number of employees were reduced to a 300-day basis whenever the schedule showed them to be the average number for a shorter period; when it was evident that the employees had worked more than 300 days, the average number for the longer period was allowed to stand. The figures for 1902, therefore, show the average number of employees that would be required at continuous employment throughout the year to perform the work done, while the figures for 1889 represent the average number employed during the actual time that the several establishments concerned were in operation and not an average number for the whole year.[2]

It is obvious that the method adopted in 1902 tends to produce a smaller average number than the method employed in 1889. This is illustrated in the statistics for several minerals as shown in this report. Thus, for example, the statistics for the production of marble, which show an increase in value of product between 1889 and 1902 of over $1,500,000, seem to show a decrease in the average number of wage-earners. Excluding the number of foremen and overseers for both years, the figures are as follows: 1889, 4,275; 1902, 4,070. But while the figures for 1902 represent the continuous employment of 4,070 men for 300 days, the average number of days worked by the 4,275 wage-earners in 1889, as the detailed statistics show, was only 255. Reduced to a 300-day basis, the average number of wage-earners for 1889 is found to be 3,648, thus showing that there has been a substantial increase during the decade.

[1] This section and the sections following, Contract Mining and Quarrying and Contract Work, were prepared by Mr. Joseph D. Lewis, chief of the division of manufactures.

[2] The difference between the two methods of computing the average is practically the same as in the statistics for manufactures of the Eleventh and Twelfth censuses and is fully explained in the Report on Manufactures for the Twelfth Census. (See Part I, pages cvi to cxi.) The instructions for verifying and correcting the number of wage-earners reported for 1902 are given in Appendix C.

It should be stated also that it is impracticable to make a comparison of the statistics of wage-earners and wages at the two censuses for the entire mining industry because the figures were not summarized for the earlier period.

Employees, by classes.—The following table summarizes the totals reported for 1902 in answer to that part of the inquiry which called for the average number of each class of salaried employees and wage-earners and the amounts paid them:

TABLE 36.—*Employees by classes: 1902.*

Salaried officials, clerks, etc.:	
Total number	38,128
Total salaries	$39,020,552
General officers—	
Number	4,591
Salaries	$8,218,541
Superintendents, managers, foremen above ground, surveyors, etc.—	
Number	15,538
Salaries	$16,666,416
Foremen below ground—	
Number	6,863
Salaries	$6,208,207
Clerks—	
Number	11,136
Salaries	$7,927,288
Wage-earners:	
Aggregate average number	581,728
Aggregate wages	$369,959,960
Above ground—	
Total average number	221,505
Total wages	$125,086,530
Engineers, firemen, machinists, blacksmiths, carpenters, and other mechanics—	
Average number	60,859
Wages	$44,478,246
Miners, quarrymen, and stonecutters—	
Average number	67,129
Wages	$33,971,290
Boys under 16 years—	
Average number	6,219
Wages	$1,339,478
All other wage-earners—	
Average number	87,298
Wages	$45,297,516
Below ground—	
Total average number	360,223
Total wages	$244,873,430
Miners—	
Average number	257,301
Wages	$184,674,193
Miners' helpers—	
Average number	18,736
Wages	$11,496,910
Boys under 16 years—	
Average number	5,638
Wages	$1,548,889
All other wage-earners—	
Average number	78,548
Wages	$47,153,438

Table 36 shows the number of all classes of employees reduced to the yearly average as above described, with the amount paid to each class in salaries and wages. Salaried officials, clerks, etc., usually receive annual or monthly salaries and, as a rule, are employed throughout the entire year; consequently, for this class, in a great majority of cases, it was unnecessary to make the reduction to the average for the year.

The employees shown in Table 36 may be arranged in two groups—first, the office force, which consisted of 15,727 general officers and clerks, receiving $16,145,829 as salaries, the number and salaries forming 2.5 and 3.9 per cent, respectively, of the totals for all employees; second, the employees engaged in supervising and in the actual work of the mines and quarries, which include the superintendents, managers, foremen, surveyors, etc., as well as the mechanics, the miners and their helpers, and all other wage-earners. This class numbered 604,129, and their salaries and wages amounted to $392,834,683, forming 97.5 and 96.1 per cent, respectively, of the totals. The superintendents, managers, foremen, and surveyors are classed as salaried officials though the distinction between foremen and miners is difficult to preserve, especially when there is very little, if any, difference in their wages.

Exclusive of the general officers and clerks, 237,043 employees, or 38.3 per cent of the total number were engaged in operations above ground, and the salaries and wages paid for such work amounted to $141,752,946, or 34.7 per cent of the total. The employees reported as engaged below ground numbered 367,086, or 59.2 per cent, and their salaries and wages amounted to $251,081,737, or 61.4 per cent of the total. The separation of employees so as to show the numbers working above and below ground can not be accepted as exact, because the same employees may, at different times, work in both places, and in some classes of mining the distinction between the two branches of work is not preserved uniformly. From Table 1, pages 348 to 361, it appears that employees working below ground were reported for the majority of the minerals; but of the total number of such employees 352,472, or all but 7,751, were employed in the mining of coal, iron, copper, gold and silver, and the salaries and wages they received amounted to $240,737,543, or all but $4,135,887 of the total salaries and wages paid for work below ground.

The miners, miners' helpers, quarrymen, and stonecutters, who may be accepted as the employees engaged in the actual work of removing the ore or mineral, and dressing the stone at the quarry, numbered 343,166, or 59 per cent of the total number of wage-earners, and their wages amounted to $230,142,393, or 62.2 per cent of the total wages.

Wage-earners, by occupations.—Table 37 shows the distribution of the several classes of wage-earners according to occupations, by minerals and groups of minerals.

TABLE 37.—DISTRIBUTION OF WAGE-EARNERS ACCORDING TO OCCUPATIONS, BY MINERALS AND GROUPS OF MINERALS: 1902.

MINERALS, BY GROUPS.	All wage-earners (number).	ENGINEERS.		FIREMEN.		MACHINISTS, BLACKSMITHS, CARPENTERS, AND OTHER MECHANICS.		MINERS, QUARRYMEN, AND STONE-CUTTERS.		MINERS' HELPERS.		TIMBERMEN AND TRACK LAYERS.		BOYS UNDER 16 YEARS.		ALL OTHER WAGE-EARNERS.	
		Number.	Per cent of all wage-earners.	Number.	Per cent of all wage-earners.	Number.	Per cent of all wage-earners.	Number.	Per cent of all wage-earners.	Number.	Per cent of all wage-earners.	Number.	Per cent of all wage-earners.	Number.	Per cent of all wage-earners.	Number.	Per cent of all wage-earners.

[1] Less than one-tenth of 1 per cent.
[2] Includes pumpmen.
[3] Includes chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile.

Table 37 shows the relative proportions of the several classes of wage-earners that were required in the different branches of the mineral industry. The schedule of inquiry, of course, could not be made in sufficient detail to show separately all classes of occupations, and consequently a large number of wage-earners that in a complete presentation would be given separately are included in the class of "all other wage-earners." A very large proportion of this class, however, were common workmen or unskilled laborers. For the industry as a whole the percentages which the numbers of the different classes of wage-earners were of the total number are as follows: Engineers, 4.5 per cent; firemen, 1.5; mechanics, 4.5; miners, quarrymen, and stone

cutters, 55.8; miners' helpers, 3.2; timbermen and track layers, 2.3; boys under 16 years, 2; all other wage-earners, 26.2.

So far as possible the minerals in Table 37 are arranged in groups according to their character or the uses to which they are put. For the reason that there is, as a rule, a similarity in the conditions of mining the minerals in the same groups, the statistics in each group are more comparable with each other than with those of different groups. A notable exception, however, is found in the group of fuels, in which the statistics for natural gas and petroleum are not at all analogous to those for coal, and are not in any sense comparable with them on account of the entirely different conditions governing production.

The conditions that chiefly affect the proportions of the several classes of wage-earners are the methods of mining, whether surface or underground, and whether the mineral is sold in the crude state or undergoes some process of manufacture at the mine before being marketed. If the mine workings are underground and are spread over a wide area, the proportion of miners is reduced and those of other classes are correspondingly increased. Conversely, in surface mining and quarrying, the proportion of those engaged in the work of getting out the mineral is, as a rule, larger than in the other branches. Any manufacturing process to which the product may be subjected at the mine or quarry before shipment necessarily increases the proportion of "all other wage-earners." This is plainly indicated in the statistics for cement, the finished cement being in every case manufactured in connection with quarrying the rock, and also to a slightly less degree in the case of gypsum, the work of manufacturing land plaster, wall or cement plaster, and plaster of Paris being done at the quarry. The proportions of "all other wage-earners" in these two industries were 58 and 51.2 per cent, respectively. The largest proportion in this miscellaneous group of employees, namely, 66.9 per cent, was for the natural gas industry, in which the principal work, after the equipment of the property is complete, is the distribution of the gas to the consumers; and the group of "all other wage-earners" was composed chiefly of the various classes of employees engaged in this part of the work. In this industry the mechanical force composed of machinists, blacksmiths, carpenters, and other mechanics, formed 23 per cent of the entire number of wage-earners. Upon comparing the statistics for petroleum with those for natural gas, it is found that the percentages for the mechanical force were almost identical in the two industries, but that in the petroleum industry the predominating class consisted of the engineers engaged in the work of pumping wells, these forming 73.8 per cent of the whole number. As shown by a comparison of anthracite and bituminous coal, the percentages for the mechanical force and for "all other wage-earners" were greater for the anthracite, while miners constituted a larger proportion in the case of bituminous. These are the natural results of the greater difficulty of anthracite mining and of the necessity of preparing the product for market after it is mined.

In addition to the foregoing and other facts that a critical analysis of Table 37 might disclose, it is shown that the mechanical force was especially large for cement, graphite, natural gas, petroleum, and talc and soapstone; that practically all the wage-earners employed were directly engaged in removing the mineral in the case of barytes, buhrstones and millstones, monazite, oilstones, whetstones, and scythestones; and that the proportion of employees included under "all other wage-earners" was considerably above the average in the case of cement, gypsum, mineral pigments, natural gas, and sulphur and pyrite.

Boys as wage-earners.—Provision was made in the schedule for reporting separately the men, and the boys under 16 years, employed as wage-earners. Table 38 shows for each mineral the number of men and boys employed, with the percentage that the number of each is of the total number of wage-earners.

TABLE 38.—*Wage-earners, men and boys, by minerals: 1902.*

[1] Less than one-tenth of 1 per cent.
[2] Includes chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile.

The average number of wage-earners employed in the mining industry in 1902 was 581,728, of whom only 11,857, or 2 per cent, were boys under 16 years, which may be considered a small proportion. The statistics of manufactures show that there were 168,583 children under 16 years out of a total of 5,308,406 wage-earners, a percentage of 3.2, employed in the manufacturing industries in 1900. The reason for the small proportion of boys employed in mines and quarries is undoubtedly the arduous nature of the work and the rigorous conditions under which it is performed in many branches of the industry. Aside from the physical strength and endurance required in much of the work, it frequently has to be performed under conditions extremely injurious to health and of great hazard to life and limb.

In many of the industries, as shown by the table, no boys were found, and in most of the others the proportion was very small. The industries for which no boys were reported are as follows: Asbestos; asphaltum and bituminous rock; borax; buhrstones and millstones; corundum and emery; crystalline quartz; flint; garnet; infusorial earth, tripoli, and pumice; lithium ore; mica; mineral pigments, crude; monazite; petroleum; precious stones; silica sand; talc and soapstone; tungsten; uranium and vanadium; chrome ore; magnesite; molybdenum; nickel and cobalt; and rutile.

It should be observed that for the mineral industries giving employment to but a small number of wage-earners in the aggregate the percentages given may be, and no doubt are, in some cases entirely misleading, as the large proportion of boys may be due to circumstances which are entirely fortuitous. The highest percentage shown is for the mining of fuller's earth, for which 24 boys, or 21.1 per cent of the total number of wage-earners, were reported. They were nearly all reported by one large establishment and were employed at the lighter work, such as driving carts and performing certain parts of the processes of drying and grinding the product. When the product, after being mined, requires some preparation before shipment, the proportion of boys is always larger than when the mineral is sold in a crude condition. This is clearly shown in coal mining, in which industry there were among the employees in both branches, anthracite and bituminous, 10,192 boys, or 86 per cent of the total for the United States in all branches of the mining and quarrying industries. In anthracite mines there were 4,564 boys employed, or 6.5 per cent of the total number of wage-earners in that industry, and in bituminous mines there were 5,628, or 2 per cent of the total. The occupations commonly followed by boys below ground are mule driving and door tending. In anthracite mines the number of boys below ground was 1.1 per cent of the total number of wage-earners, and in bituminous 1.7 per cent, showing that a somewhat larger proportion of boys was required in underground work in bituminous mining than in anthracite. As a rule bituminous coal requires no preparation after being mined; the "run of mine" is usually marketed in that condition. Anthracite, on the other hand, is always crushed, screened, picked or cleaned, and in many instances washed before being shipped, and many boys are employed in the various stages of the process. This is clearly indicated by the statistics. In bituminous mining only three-tenths of 1 per cent of the total number of wage-earners were boys working above ground, while in anthracite mining such employees formed 5.5 per cent of the entire number.

It is especially noteworthy that for gold and silver mining, in which on an average 36,142 wage-earners were employed, only 27 boys, or one-tenth of 1 per cent of the total, were reported, and of this number only 6 worked underground. The number of boys reported in copper and in lead and zinc mining was also noticeably small.

Wage-earners employed during each month.—The statistics for the average number of wage-earners employed each month are summarized in the following table:

TABLE 39.—*Average number of wage-earners employed during each month: 1902.*

	Total.	Men 16 years and over.	Boys under 16 years.
Yearly average	581,728	569,871	11,857
January	605,802	590,362	15,440
February	602,635	587,181	15,454
March	611,026	595,413	15,613
April	620,166	604,359	15,807
May	566,870	556,464	10,406
June	525,464	518,197	7,267
July	516,870	509,596	7,274
August	528,532	521,089	7,443
September	537,433	529,932	7,501
October	575,796	566,591	9,205
November	646,922	631,639	15,283
December	643,220	627,629	15,591

The greatest number, 646,922, were employed in November. Exclusive of the coal mines, the greatest activity in the mining industries was during the summer months, the largest number being employed in August. The largest number were employed in the coal mines during December, but the strike in the anthracite coal region continued from May to October and greatly reduced the number employed during that period. The number employed each month in the production of the different minerals, shown in Table 40, indicates that in some branches of mining the operations were comparatively constant during the year, while in others the activity of the industry varied widely.

There is a natural division of mining operations into two main classes, surface and deep mining. Activity in the former is affected, as it is in outdoor industries generally, by the weather and by seasonal changes; while operations in the latter class, as a rule, are governed more by the market conditions. No idea can be

obtained from Table 39 of the periods of activity and depression in particular branches of the mining industry, although it shows general conditions for the industry as a whole. It is not practicable to make a complete segregation of the statistics based on this division, as operations in some of the industries, iron ore for example, are conducted both on the surface and underground.

Reference to the detailed statistics in Table 1, page 348 of this report, will show for each branch of the mining industry the variations in the average number of wage-earners employed during each month. Table 40 shows the average number of wage-earners employed each month for the more important minerals—that is, those showing a yearly average of more than 2,000 wage-earners.

TABLE 40.—AVERAGE NUMBER OF WAGE-EARNERS EMPLOYED DURING EACH MONTH, BY MINERALS, IN THE MINING OF WHICH MORE THAN 2,000 WERE EMPLOYED: 1902.

MONTH.	All minerals.	Cement.	Clay.	Coal, anthracite.	Coal, bituminous.	Copper ore.	Gold and silver.	Iron ore.	Lead and zinc ore.	Limestones and dolomites.	Marble.	Natural gas.	Petroleum.	Phosphate rock.	Sandstones and quartzites.	Siliceous crystalline rocks.	Slate.	All other minerals.

December	643,220	14,071	2,293	118,602	303,140	25,732	34,707	39,217	8,202	26,231	3,940	6,337	18,001	5,751	7,790	15,789	5,659	7,758

Of the minerals shown separately in Table 40, the production of clay appears to have been carried on with the greatest degree of regularity, the number employed varying only from 2,658 in June to 2,128 in February, while the number employed in the production of anthracite coal varied from 119,228 in February to 6,552 in July. This wide variation marked an abnormal condition—the great strike, which continued from May to October. While it seems that the strike affected all of the wage-earners in the coal industry, the operators were successful in most cases in securing the services of a sufficient number of men to protect their properties and to preserve them from deterioration and, in some instances, even to mine small quantities of coal.

In bituminous coal mining the largest number of wage-earners, 303,140, appears for December. The number fluctuates from month to month, reaching the lowest point, 260,817, in July.

Table 40 clearly indicates that in all kinds of mining and quarrying, where the work is done largely in the open air, the period of greatest activity is in summer, while the averages for the winter months denote a time of comparative depression. This condition is shown for clay, limestones and dolomites, marble, sandstones and quartzites, siliceous crystalline rocks, and slate, and also, although less pronounced, for cement, iron ore, and lead and zinc ore. Phosphate rock, being mined almost entirely in the South where the seasonal changes have less effect, shows a less marked reduction of the number of employees in the colder months than some of those just mentioned.

The variation in the average number of wage-earners in gold and silver mining was from 37,333 in June to 34,705 in January, and in copper mining from 27,183 in May to 24,768 in February.

Average earnings of wage-earners.—In considering the statistics of employees and wages included in this report it should be understood that it is not possible to draw from the figures any trustworthy conclusion regarding the average earnings of all those employed at stated wages, either by the day or piece. The division of the total amount paid in wages to the wage-earners of any industry or of any class by the number of wage-earners in the industry or class results in an unreal and deceptive amount, which is the quotient of the mathematical operation and nothing more. It does not represent the rate of wages of any one class of wage-earners.[1]

A part of the inquiry into employees and wages was framed for the purpose of bringing out the actual daily rates of pay received by the different classes of wage-earners, and this division of the general subject is treated on pages 96 to 101 of this report. While this class of wage statistics, i. e., actual wage rates, appears to receive the more general approval of statisticians, in preference to statistics purporting to represent average earnings, these rates, unless considered in connection with the duration of the period of employment, are liable to prove misleading. While a given rate represents the earnings of each wage-earner at that rate for a day's employment, it fails to furnish a true indication as to the annual earnings of the workman, and so falls short of being a correct index of his economic condition, which is better determined by the amount of wages paid to him annually. This is perhaps true more

[1] This question is fully discussed in the Report on Manufactures for the Twelfth Census. (See Part I, pages cxi to cxxv.)

especially of mining and quarrying than of other lines of industry, as operations are frequently very irregular and spasmodic by reason of a fluctuating demand for the products.

The statistics for anthracite coal may be taken as illustrating these points. Table 40 shows that for 1902 the least number of men, 6,552, was reported for July, and the greatest number, 119,228, for February. The strike of the anthracite coal miners lasted from May 12 to October 23, and the number employed in July may be said to represent the minimum, or the number required to preserve and protect the properties; while the number for February, giving due consideration to the fact that it is an average for the month, is the full quota finding employment in the industry. The amount paid in wages during the year was $38,716,113, and the division of this amount by the average number of wage-earners for the year, 69,691, results in a quotient of $555, which can be regarded only as an abstract quantity indicating the measure of the earnings of a theoretical average employee who worked full time during the year. This, in the light of the actual experience of those employed at anthracite mines in 1902, can only be considered as an ideal state of affairs.

Wage-earners at specified daily rates of pay.—The inquiry designed to elicit the daily rates of pay of the wage-earners called for a distribution of the several classes according to their rates by 25-cent groups from 50 cents to $4.24, those receiving less than 50 cents and those receiving $4.25 or over to be combined into single groups. The exact rate of pay was not asked for, and in most cases the distribution of the employees within the 25-cent groups is not definitely known. It may be stated as a general proposition, however, that the greater proportion of the wage-earners included in the various 25-cent rate groups received the lowest rate of those groups. In the case of coal and iron ore miners and other employees paid in accordance with the amount of work done, very little can be said regarding daily rates of pay. When wage-earners are paid by the hour there is the same difficulty, for the daily rates are then naturally dependent upon the hours of employment. However, with the exception of coal and iron ore miners and some quarrymen, the great majority of the wage-earners employed in the mineral industries of the United States are paid by the day; and when employees are paid by the day their rates are more likely to be in multiples of 25 cents than otherwise. For example, the returns show that 6,742 of the men employed in copper mines received between $3.50 and $3.74 per day, and it may be safely stated that most of these men received $3.50 a day. For some minerals the daily rates of the several occupations are fixed at figures which are not multiples of 25 cents. But it would be more nearly correct to take the lowest rate in most wage groups as the rate paid to the greater number of the employees included within that group than it would be, for example, to consider the rate halfway between the limits of the group as an average for the entire group.

The distribution of the wage-earners according to these rates is shown in the following table for each mineral in the production of which more than 1,000 wage-earners were employed on the average during 1902. The table gives also the per cent that the number at each rate is of the total number; and the cumulative percentage at each rate, which shows what proportion of the total number received a wage as great as, or greater than, the lowest wage of the given wage group.

TABLE 41.—DISTRIBUTION OF WAGE-EARNERS ACCORDING TO DAILY RATES OF PAY, BY MINERALS: 1902.

[Each cumulative percentage shows the proportion of the total number receiving a wage as great as, or greater than, the lowest wage of the given wage group.]

[1] Less than one-tenth of 1 per cent.

The production of the minerals for which separate statistics are shown in Table 41 gave employment to 576,507 wage-earners, this number forming 99.1 per cent of the 581,728 wage-earners reported for all mines and quarries. The average number and per cent of the total number are shown in the table for each rate group. The percentages are also accumulated.

The cumulative percentage is obtained by combining the figures which represent the per cent of total. For example, in Table 41, under the head of "all minerals," four-tenths of 1 per cent of the wage-earners received $4.25 or over and seven-tenths of 1 per cent received between $4 and $4.24; adding the two percentages, it is found that 1.1 per cent received $4 per day or over.

This process is continued throughout the wage scale until all the wage-earners have been included, when the cumulative percentage naturally becomes 100 per cent. The cumulative percentage, as stated opposite any wage group, shows then the percentage of the total number formed by the sum of the number included in that wage group plus the number included in all the higher wage groups.

Two advantages are gained by the use of the cumulative percentage. In the first place, it is possible to determine at a glance the proportion of the total number receiving as much as, or more than, a given rate. For example, if the cumulative percentages were not given in the preceding table, and it were desired to obtain the proportion of the total number who received $1.50 per day or over, it would be necessary to add the nine numbers representing the percentages at each rate from $1.50 up. In the cumulative percentage column this addition is already made, and it is evident at a glance that 60.1 per cent of the cement workers received at least $1.50 per day.

The second advantage gained by the use of the cumulative percentage lies in the fact that it is possible to compare two given sets of returns much more readily than by either the numbers or the percentages in the respective groups. For example, in Table 41 the column headed "cumulative percentage" shows that for cement workers the proportion of the total number receiving $1 per day or more was 98 per cent, while for clayworkers it was 84.2 per cent. At $1.50 the respective proportions were 60.1 and 28.1 per cent, and at $2 they were 16.1 and 11.2 per cent. The cumulative percentages thus show that wages were higher in 1902 for cement workers than for workers in clay mining.

Of the various minerals for which statistics are shown separately in the above table the production of anthracite and bituminous coal gave employment to the greatest number of wage-earners. A very large proportion of the miners in the coal mines were paid according to the quantity of their product, and some of the principal coal companies were unable to classify these employees according to the specified daily rates of pay. When data of this character were not reported by the company estimates were made in the Bureau of the Census from the total number of such employees reported, the total amount of wages paid, and the number of days that the mine was in operation, the rate being determined by the average daily earnings for the time employed, and the average number for the entire year being computed as previously explained; therefore, in such cases all employees of a mine who were paid by the piece or quantity of work done as measured by their output were estimated as receiving a uniform daily rate of pay. There were 230,846 employees reported as the average number receiving wages according to the quantity of their production, and they were paid $155,578,988. Of this number, 211,710, or 91.7 per cent, were reported for anthracite and bituminous coal, and they received $144,628,436, or 93 per cent of the amount paid for such mining in all minerals.

When the figures for all minerals are combined, it is found that the range of wages for practically all of the wage-earners was from $1 to $3.74 per day, 556,531, or 95.7 per cent of the total number employed, being included between those rates. Less than 3 per cent of the total number received less than $1 per day, and only 1.5 per cent received $3.75 or over. The four rate groups that lead in the number of employees included are consecutive and constitute the range from $1.50 to $2.49 per day. Between those limits is included 58.1 per cent of the total number. It should be added, however, that the proportion at $2.50 or over is much greater than that at less than $1.50. Of the total number of wage-earners, 57.2 per cent were paid $2 per day or more. An attempt to find the median rate (that is, a rate such that half the number of wage-earners receives that rate or more and the other half receives that rate or less) discloses the fact that this rate lies somewhere in the group $2 to $2.24. It will also be noticed that the rate group that includes the median includes a greater number of wage-earners than any other group in the scale.

In regard to the various minerals, the figures shown in Table 41 may be briefly summarized as follows:

Cement: Of the total number of wage-earners, 73.5 per cent were paid from $1.25 to $1.99.

Clay: The range of wages for 82.9 per cent of the total number was from $0.75 to $1.74; 35.8 per cent were included in the single rate group $1.25 to $1.49.

Coal: For a large number of coal miners the figures given represent average earnings and not rates, as most of these employees are paid by the ton or other unit. As the figures stand, they show that for anthracite coal 75.7 per cent of the employees received between $1 and $2.49, and for bituminous coal 76.9 per cent received between $1.50 and $2.74.

Copper ore: A wide range is noticeable in the wages paid to employees engaged in copper mining. Of the total number 24.1 per cent received between $2 and $2.24, and 25.9 per cent were paid from $3.50 to $3.74; the remaining wage-earners were distributed in smaller groups throughout the scale from $0.50 to $4.25 and over.

Gold and silver: Employees engaged in the mining of gold and silver were largely concentrated in three groups as follows: 15.3 per cent from $2.50 to $2.74; 33.7 per cent from $3 to $3.24; and 19 per cent from $3.50 to $3.74.

Gypsum: The range of wages for 84.4 per cent of the wage-earners was from $1.50 to $2.24; 51.2 per cent received from $1.50 to $1.74.

Iron ore: Of the total number of wage-earners, 86.8 per cent received between $1 and $2.49; the greatest concentration was at $2; 40.9 per cent of the total number received between $1.75 and $2.24.

Lead and zinc ore: Almost all, 91.3 per cent, of the wage-earners received between $1.25 and $2.49 per day; 26 per cent receiving from $1.50 to $1.74; and 29.2 per cent from $2 to $2.24.

Limestones and dolomites: The range of wages for 91.2 per cent of the total number was from $1 to $2.24. Here again there was a marked concentration at two rate groups, 24.9 per cent receiving from $1.25 to $1.49, and 29.1 per cent from $1.50 to $1.74.

Marble: The returns for wage-earners engaged in quarrying marble show a less marked concentration than is observable in most other minerals. There were, however, 58.5 per cent of the total number between the rates $1 and $1.74.

Natural gas: For 92.5 per cent of the wage-earners the range was from $1.25 to $2.74. The two wage groups showing the greatest number are as follows: $1.50 to $1.74, 26.3 per cent; $2 to $2.24, 23.3 per cent.

Petroleum: For 70.7 per cent of the total number of wage-earners the range of wages was from $2.25 to $2.74 per day, 57.2 per cent being included in the single rate group $2.25 to $2.49.

Phosphate rock: Almost all the wage-earners received less than $1.25, 82.8 per cent getting between $0.75 and $1.24. In the wage group $1 to $1.24, there were 61.2 per cent of the total number.

Quicksilver: The range of wages for the bulk of the employees was from $1.25 to $2.74, 81.6 per cent being included within those rates.

Sandstones and quartzites: The range of wages for 73.1 per cent of the total number was from $1.25 to $2.24.

Siliceous crystalline rocks: The figures show less concentration than for most of the other minerals; more than half, 59.3 per cent, of the total number, however, received between $1.25 and $2.24 per day.

Slate: In the quarrying of slate the rates for 81.5 per cent of the total number of wage-earners ranged from $1.25 to $2.49. The greatest concentration was in the wage group $2 to $2.24, which showed 23.1 per cent of the total number.

An examination of the cumulative percentages shows that wages were far higher for employees in gold and silver mines than for any other mineral, 66.5 per cent of all the wage-earners receiving $3 or over. Employees in copper mines were next highest paid, 29.9 per cent receiving $3.50 or over, and 77.5 per cent getting at least $2. Of the men employed in connection with petroleum wells, almost 90 per cent received $2 or over, but only 9 per cent of these received as much as $3. After gold and silver, copper, and petroleum the minerals showing the highest rates of wages are bituminous coal, quicksilver, natural gas, sandstones and quartzites, and siliceous crystalline rocks, in the order named. Following these come a large class of minerals which show very little difference in daily rates of pay, when all the wage-earners are considered as one group without distinction as to geographic location or specified occupation. These minerals are anthracite coal, iron ore, lead and zinc ore, marble, and slate. As will be shown later, when these minerals are considered by states and the wage-earners separated into the several classes, considerable variation in the rates are found. The rates of pay for men employed in quarrying phosphate rock were lower than those for any other mineral, only 14.8 per cent getting as much as $1.25 a day. This industry was practically confined to Florida, South Carolina, and Tennessee.

The number of wage-earners employed in the different occupations is an important factor to be considered in connection with these statistics, and the following table summarizes the returns for all minerals so as to show the average number receiving stated daily rates of pay in each occupation and the percentage which the number at each rate forms of the total number in the class:

TABLE 42.—AVERAGE NUMBER OF WAGE-EARNERS, AND PER CENT OF TOTAL NUMBER, AT SPECIFIED DAILY RATES OF PAY, BY OCCUPATIONS: 1902.

RATE PER DAY (DOLLARS).	ALL WAGE-EARNERS.		ENGINEERS.[1]		FIREMEN.		MACHINISTS, BLACKSMITHS, CARPENTERS, AND OTHER MECHANICS.		MINERS, QUARRYMEN, AND STONECUTTERS.		MINERS' HELPERS.		TIMBERMEN AND TRACK LAYERS.		BOYS UNDER 16 YEARS.		ALL OTHER WAGE-EARNERS.

[1] Includes pumpmen employed at petroleum and natural-gas wells.

[2] Less than one-tenth of 1 per cent.

Of the total number of wage-earners considered in the preceding tables, 11,857 were boys under 16 years of age, and nearly all of them received less than $1.25 per day. It will be noticed that the employees in the three lowest wage groups were very largely boys. For all occupations combined the range of wages for 58.1 per cent of the total number was from $1.50 to $2.49 per day. For 16.4 per cent the rates were less than $1.50, and the balance, 25.5 per cent, received $2.50 or over. Of the miners, quarrymen, and stonecutters, 66.6 per cent received between $1.50 and $2.74 per day, leaving 11.4 per cent who received less than $1.50 and 22 per cent who received $2.75 or more. The group of "all other wage-earners" is the next most important class in point of numbers. The figures for this class of employees show the following distribution: Less than $1.25, 11.5 per cent; between $1.25 and $2.24, 69.9 per cent; $2.25 or over, 18.6 per cent. There is a marked excess at the higher rates of pay for engineers, 70.1 per cent receiving $2.25 a day or over; a very large proportion of these were pumpmen employed at petroleum wells. The great majority of the timbermen and track layers were concentrated in the three groups between $1.75 and $2.49, 70.3 per cent being included between these rates. There was less concentration among the miners' helpers, the range of wages for 70.6 per cent of them being from $1.25 to $2.49.

The distribution of wage-earners according to daily rates of pay, by states and territories, is shown in the following table:

TABLE 43.—AVERAGE NUMBER OF WAGE-EARNERS AT SPECIFIED DAILY RATES OF PAY, BY STATES AND TERRITORIES: 1902.

STATE OR TERRITORY.	Total.	Less than $0.50.	$0.50 to $0.74.	$0.75 to $0.99.	$1.00 to $1.24.	$1.25 to $1.49.	$1.50 to $1.74.	$1.75 to $1.99.	$2.00 to $2.24.	$2.25 to $2.49.	$2.50 to $2.74.	$2.75 to $2.99.	$3.00 to $3.24.	$3.25 to $3.49.	$3.50 to $3.74.	$3.75 to $3.99.	$4.00 to $4.24.	$4.25 and over.

[1] Includes the employees of 2 operators in Alaska and of 1 operator in Hawaii.

Only the state totals are shown in the above table, the statistics for the various minerals in each state and for the several classes of employees being combined. The distribution of the various minerals throughout the United States differs so much that, while this table is of interest as showing the total number of wage-earners at the various rates of pay in the several states, a comparison of the rates paid in one state with those paid in

another is of little value unless the minerals in each state are kept in mind. Thus, according to the figures presented, rates were highest in Montana and lowest in Florida. But since the greater part of the wage-earners in Montana were employed in copper and gold and silver mines, while those in Florida were employed in quarrying phosphate rock, the difference in wages is hardly significant.

It will be observed that the states reporting a large number of employees at the low rates are Southern states, while those reporting the greatest proportion at high rates are Western states. The difference in wages, according to geographic location, is more clearly shown in the following table, in which the figures for the various states are combined in five groups. The percentage of the total number at each rate is given for each group, as are also the cumulative percentages.

TABLE 44.—DISTRIBUTION OF WAGE-EARNERS ACCORDING TO DAILY RATES OF PAY, BY GEOGRAPHIC DIVISIONS: 1902.

[Each cumulative percentage shows the proportion of the total number receiving a wage as great as, or greater than, the lowest wage of the given wage group.]

[1] Less than one-tenth of 1 per cent.

As shown by the above table, rates were much higher in the Western division than in any of the others, 51.8 per cent of the wage-earners in that division receiving $3 per day or over. The three rate groups showing the greatest number of employees are as follows: $2.50 to $2.74, 15.6 per cent; $3 to $3.24, 22.8 per cent; and $3.50 to $3.74, 18.3 per cent. In this group of states are included almost all of the gold and silver and copper mines of the country.

The wages in the North Central division were considerably lower than those in the Western division, but higher than those in either of the three other divisions. The range of wages for the majority of the employees, 83.3 per cent, was from $1.50 to $2.74, the rate group showing the greatest number of wage-earners being that of $2 to $2.24, which includes 28.7 per cent of the total number. In this North Central division are included the iron mines of Michigan and Minnesota, the coal mines of Ohio, Indiana, and Illinois, and the oil wells of Ohio and Indiana.

The rates of pay in the North Atlantic division were only slightly lower than those in the North Central division. The bulk of the employees received between $1.25 and $2.49 per day, 73.2 per cent being included between those rates. Over 70 per cent of the wage-earners in this division were employed in the coal mines of Pennsylvania.

Wages were lowest in the South Atlantic and South Central divisions, there being very little difference between the two sections. In each section 78.8 per cent of the total number were included between the rates $1 and $2.49.

IX.

CONTRACT MINING AND QUARRYING.

By reference to the copy of that part of the schedule of inquiry which relates to employees and wages, shown in Appendix A, it will be seen that operators were required to report mining or quarrying which was paid for otherwise than by the day. The inquiry was made a part of the schedule in order to determine the conditions of employment of those engaged in the actual work of mining and the extent to which such work was done under other terms of payment than daily rates. To indicate the extent to which such work was done in the different kinds of mining, Tables 45 and 46 are shown. Table 45 gives the total average number of miners and miners' helpers, and quarrymen and stonecutters, with the amount paid in wages to this class of employees; also the average number of contract miners, with their wages and the percentage the number of contract miners forms of the total number of men engaged in mining and their wages form of the total wages, respectively.

All other minerals[2]	14	9,411	3	21.4	1,575	16.7

[1] Less than one-tenth of 1 per cent.
[2] Includes chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile.

It should be understood that the contract miners and quarrymen reported in the above table were not employees additional to those shown under wage-earners by classes, but are included there and also in the tables showing wage-earners by specified daily rates of pay and the average number employed during each month.

Of the total number, 343,166, engaged in actual mining aside from the other supplemental but necessary work about mines, such as timbering, track laying, operating engines and pumps, etc., 230,846, or 67.3 per cent, were paid by the amount of work done. They received in wages $155,578,988, or 67.6 per cent of the total wage payment.

It will be observed that the statistics for petroleum and natural gas are not shown in the foregoing table. In these industries the regular employees are almost entirely engaged in the maintenance and operation of the wells, and there are no employees that could be classified as "miners and miners' helpers or quarrymen and stonecutters." The initial work of developing oil and gas properties—drilling wells and building rigs—is practically all done by outside contractors, and the cost of such work is given in Table 47.

The following industries are those for which no contract mining was reported and in which payment for mining, in all cases, was by the day: Bauxite, borax, corundum and emery, crystalline quartz, fluorspar, fuller's earth, garnet, graphite, lithium ore, manganese ore, marl, mica, precious stones, tungsten, uranium and vanadium, magnesite, molybdenum, nickel and cobalt, and rutile.

In the coal industry practically all the employees who are engaged in cutting the coal and loading it into cars in the mine are paid by the car, ton, or yard. In bituminous coal mining 189,081 miners and miners' helpers, or 98 per cent of the total number of this class of workmen, were paid by the piece; in anthracite mining 22,629, or 91.7 per cent of the total for the industry, received wages by the piece. The amounts paid in the two industries were $128,055,854, or 98.2 per cent, and $16,572,582, or 92 per cent, respectively.

A feature of wage payment which distinguishes coal mining from other branches of the mining industry is the custom of "allowance," which obtains to a greater or less degree in nearly all coal mining operations. There are so many complex influences affecting the amount of payment to miners working by the ton, car, yard, or otherwise than by the day, that it is sometimes considered expedient and equitable to make payment for yardage—the number of linear yards which the "chamber," "heading," or "breast" in which the miner works may have been driven during the time for which payment is made, in addition to the earnings which may have accrued from the regular rate by the car or otherwise; also to make additional allowances in consideration of difficult mining, narrow work, or for other causes. This is done in order to equalize the earnings of the miners; otherwise it might frequently be the case that the harder working and in other respects more deserving employee would receive less pay than one whose output was smaller and hours of work fewer. While it may be customary to make similar allowances in other mining industries, it certainly can not be so to the same extent, and therefore no provision was made in the general mining schedule or in any of the other schedules, except for coal, for a separate report of such payments. The following table shows, for coal by states, the total amount paid in wages to contract miners and, in an adjoining column, the amount of such wages which was paid for yardage or other allowances and the percentage

which the latter is of the total wages. The number of mines at which payment was reported by the ton, car, yard, or other unit is also given.

TABLE 46.—*Wages paid for contract coal mining, and amount paid in allowances, by states and territories: 1902.*

[1] Includes Idaho and North Carolina.

Table 46 shows that the amount paid for yardage or other allowances in coal mining, both anthracite and bituminous, was $10,970,567, which was 7.6 per cent of $144,628,436, the total amount paid for contract coal mining. The prevailing method of payment for contract coal mining in bituminous mines was by the ton, as there were 4,018 mines for which this method was reported, compared with 317 by the car, 20 by the yard, and 6 by other methods. The total number of mines reporting some method of contract mining was 4,648. The difference between this number and the total number of coal mines reported for the United States is 1,338, and is accounted for by the number of mines in which a daily rate of pay was the rule, and by the small "local coal banks" at which no wage-earners were employed. In several instances more than one of these methods was reported for the same mine. In anthracite coal mining, the prevailing method of payment was by the car, 254 mines reporting that method, as compared with 26 by the ton and 7 by the yard.

It should be stated that when payment by the yard is in the form of allowance only, it has not been included in Table 46 as a method of payment.

The subject of allowances in addition to the regular schedule of rates for coal mining receives the careful consideration of both the operators and the miners. The fact that 7.6 per cent of the wages paid for contract work was in the form of allowances indicates the prime importance of this feature of wage payment in the economical administration of the properties. Without this system no equitable and uniform scale of wages could be arranged.

These allowances are nearly always fixed by the foreman in charge of the mine, and usually result from a conference as to the equities of the case between him and the miner interested. It will be observed that according to Table 46 allowances were made in every state and territory separately shown, the amount ranging from $3,940,090 for both anthracite and bituminous in Pennsylvania to $2,700 in Oregon, and the percentage that the allowance is of the total wages paid for contract mining from 21.4 per cent in Michigan to 2.8 per cent in Virginia.

The schedule called for the rate of payment by the ton, car, yard, or otherwise, and a mass of information was received bearing upon this point. However, the very wide range of the rates and the complexities of the subject generally have defeated any statistical presentation of the data reported.

The amount paid for contract mining in the iron ore industry was $5,090,832, which was 42.8 per cent of the total amount paid to miners in that industry. The number of wage-earners so employed was 8,105, or 38.9 per cent of the total number of miners. Payment for contract mining in this industry was principally by the ton and by the tram, and occasionally by the yard, with a wide range of rates.

The number of contract wage-earners engaged in quarrying limestones and dolomites was 3,772, or 17.1 per cent of the total number of contract quarrymen and stonecutters, and the amount of wages paid was $1,482,678, or 14.5 per cent of the total for such work. The unit upon which payment was based was very irregular, as payment was reported by the tram, ton, foot, yard, perch, and bushel.

In gold and silver and lead and zinc mining the proportion of contract mining was very small and indicates that most of the work was done by the day. In lead and zinc mining contract mining was exceptional, as the amount reported was only $266. In those mines, however, where the landowner or first lessee was also the buyer of all ore mined by the sublessees, the latter were virtually wage-earners paid by the ton. The total number of such sublessees reported was 638 and the total amount paid to them was $244,661; out of this amount they were required to furnish their own supplies. In the tabulation of the statistics these sublessees in lead and zinc were regarded as proprietors and are not included in Table 46.

Contract mining was reported for only a small number of copper mines, and these were all in Michigan, no work of that kind being reported for the argentiferous copper mines of the Rocky mountain region. The average number of contract miners was 2,206, or 15.7 per cent of the total number, and the amount paid was $1,601,091, or 12.9 per cent of the total wages paid for mining copper ore. Drifting, as reported, was paid for by the foot, the rate ranging from $5.75 to $7.71. Stoping was paid for at an average of about $8 per cubic fathom.

In barytes mining 71.1 per cent of the miners worked by the piece system, and according to the reports, received payment by the ton, the rates ranging from $2 to $3.50.

Only a comparatively small percentage of cement-rock mining was done by contract. Payment in such cases was by the ton and there was a wide range of rates.

Contract clay mining was paid for by the ton, the rate ranging from 13½ to 75 cents per ton.

The rate paid for mining gypsum on contract ranged from 20 to 65 cents per ton, with most of the operators reporting a rate between 40 and 50 cents.

Thirteen and three-tenths per cent of the wages paid for quarrying sandstones and quartzites was for contract quarrying. The unit upon which payment was based in this industry was the same as in the quarrying of limestone and dolomites and siliceous crystalline rocks, very irregular, as payment was reported by the tram, ton, foot, yard, perch, and bushel, and the rates varied more widely.

A large proportion, 68.5 per cent, of the mining of crude mineral pigments was by the ton; the lowest rate reported was 40 cents and the highest $5 per ton.

Most of those engaged in monazite mining, while working independently of any proprietors, were reported as wage-earners on contract, as elsewhere described. The crude monazite obtained from the placers was sold by the miners at the rate of 4 cents per pound, and this was treated in the statistics as the rate received by them for contract mining.

Approximately one-fourth of the mining for phosphate rock was by contract. In a few instances payment was made by the car and yard, but in most cases it was by the ton. The rates ranged from 25 cents to $5 per ton. The latter amount was paid by an establishment in New Mexico, where the product was a bat deposit found in a cave and difficult and expensive to mine on account of its location.

Contract slate quarrying was by the square, and the lowest rate reported was 70 cents and the highest $2.25.

As shown by Table 45, there were several other industries for which small proportions of contract mining were reported, but the amount and percentage of the figures are comparatively unimportant.

X.

CONTRACT WORK.

In nearly all branches of the mining and quarrying industry occasions arise which demand considerable outlays for work that is different from the regular production of the ore or mineral—work such as tunneling, shaft sinking, boring test holes, and removing top earth where open-cut mining is intended—and this is frequently let to contractors who make a specialty of the work in question, usually to the lowest bidders. Table 47 shows for each mineral the value of the product, the amount paid for contract work and the number of employees engaged in it, and the per cent that the amount paid for this work is of the value of product.

TABLE 47.—*Comparison of contract work with value of product, by minerals: 1902.*

MINERAL.	Value of product.	CONTRACT WORK.		Per cent amount paid for contract work forms of value of product.
		Amount paid.	Number of employees.

[1] Less than one-tenth of 1 per cent.
[2] Includes chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile.

When the schedule of inquiry was drawn up the difficulty of obtaining complete and correct information in regard to contract work, especially concerning the

number of men employed and the number of days required to complete the work, was fully appreciated by the officials of the Bureau of the Census and by experts who were consulted in the preparation of the schedule. It was believed that in most cases it would be impossible to locate the contractors. Generally no record is kept by the mine operators of any other data relating to contract work than the amount paid. The number of employees and the duration of the contract are matters of less concern to them. However, it was thought that the close attention they are obliged to pay to the work during its progress to insure strict compliance with the terms and specifications of the contract, would enable them, in the absence of records, to make a fair estimate of the data. This was realized in the course of the canvass, and the statistics are published with no pretentions that they can be regarded as strictly correct, but under the conviction that they are reasonably accurate considered as statistics which are in part estimated.

The employees reported under this inquiry are not included among the wage-earners and should not be considered as forming a part of the wage-earners reported by classes, and at specified daily rates of pay, nor of the average number reported for each month. No conclusions can be drawn from Table 47 as to the amount paid to contract employees, nor in regard to the average number for the entire year. As to the latter, indeed it is quite possible that some of the employees are duplicated in the figures.

The amount paid represents the entire cost of the contract work, including the wages paid, the cost of all supplies and materials used, other miscellaneous expenses, and the profits of the contractors. These expenses vary in their proportion to the whole cost according to the kind of work. In drilling wells for petroleum and natural gas, as a rule the cost of materials is greater in proportion than in any other description of contract work. The drilling carries with it the obligation to provide casing, tools, and all other supplies required to equip the wells; and in building the rig, all materials are generally furnished by the contractor. In shaft sinking, also, materials and supplies such as timber and explosives form a considerable proportion of the whole cost.

While no particular statistical value can be attached to a comparison of the cost of contract work with the value of product, yet always keeping in mind the fact that the figures are not fully representative of this class of work, a great deal of it being done by the regular employees of the mining companies, the table will serve to show the proportions of both with respect to the value involved.

Table 47 shows that the amounts paid for contract work and the percentages that these form of the value of the product are greater in the case of petroleum and natural gas than for any other mineral. In the crude-oil and natural-gas industry practically all of the development work, prospecting, and equipment of the properties are done by contract, which explains the large amount expended for such work. The regular employees of the producing companies are nearly all engaged in the maintenance and operation of the wells. The number of employees reported as employed on contract work in this industry approaches more nearly the true average number for the year than in any other.

As explained on page 20 of this report, the Standard Oil Company made reports covering the entire production of crude petroleum, with the exception of a few producers of heavy oil, in Pennsylvania, New York, Ohio, West Virginia, and Indiana, and combined reports of its own production for Kentucky and Kansas, without separating the production by counties, as was generally required by the Bureau of the Census. Also, for natural gas the company reported for its subsidiary or contributary companies the production in Pennsylvania, New York, Ohio, and West Virginia, making a single report for each state. In reporting contract work the amount paid was given, but it was stated that the number of men employed could not be given, and in lieu of exact information the average number of men required for each well and rig and the average time required to complete the work at each well were reported. From these data, using as a basis the number of wells drilled during the year and assuming that operations were continued throughout the whole year on full time, the average number of men employed was computed. While the figures, therefore, are pure estimates, if the information furnished by the company is accurate they may be accepted as fairly representing the statistics for this branch of the industry. Taking into consideration the fact that the amount paid for contract work in the petroleum and natural-gas industries, $17,415,632, is 84.2 per cent of the total paid in all mining and quarrying industries, $20,677,938, and that the number of employees in these industries, 11,217, is 53 per cent of the total, 21,183—with the additional consideration of the great preponderance of the Standard Oil Company's interests over those of all other oil producers—an idea is obtained of the extent to which the total number of employees engaged in contract work in all the industries is affected by the estimates which were made necessary.

The amount paid for contract work in coal mining was $1,650,535; in anthracite $406,421, and in bituminous $1,244,114; and the number of employees was 6,771—in the former 1,731, and in the latter 5,040. The information was generally reported by the coal operators very completely. No reduction of the number of employees reported to the average number for the year was made, and the number given in the table

may contain duplications, as there was nothing in the reports to show whether or not a force of employees engaged in a contract and so reported was not again reported for another contract, taken after the completion of the first for a different operator and both during the census year 1902. Unlike those engaged in deep mining for the precious metals—for copper, iron, etc.—coal miners, engaged as they are in mining a material more easily worked than the surrounding rock and which is always found in well-defined veins, are usually unsuited for what is termed "rock work." Therefore such work as tunneling, shaft sinking, boring test holes, etc., is in most cases done more economically under the contract system. The larger companies, however, frequently maintain a force of men especially for that purpose.

The amount reported as paid for contract work in gold and silver mining was $626,090, which was only eight-tenths of 1 per cent of the value of the product of the mines. The work was very similar to development work in other kinds of mining. In some cases, where considerable depth had been reached and pumping had to be done on an extensive scale, it was at times impossible for one mining company to pump the water from its mine without at the same time clearing all adjacent mines. This work was therefore most conveniently done by contracting firms or companies with whom the business had become a specialty.

The amount paid for contract work in iron ore mining was $425,292, and there were 1,079 men employed. The work was similar in character to that done in other branches of the mining industry, except that there may have been a larger proportion of stripping preparatory to open-cut mining.

It should be explained that in the data shown in Table 47, in addition to the amount paid for work other than mining which was done by contract, there is included the amount paid by private operators to state and municipal penal institutions for the lease or use of convicts in the operation of mines and quarries. A careful examination of the reports received shows that $530,341 was paid for this purpose. The laws of certain Southern states permit the lease of convicted prisoners to private persons or firms for work outside of the penitentiaries. Among the states by which this is done are Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, North Carolina, South Carolina, and Tennessee. This is entirely apart from the work of convicts in mines or quarries owned by the state. The only states in which the convicts were reported to have been leased to work in mines and quarries, and to which the amount above reported, $530,341, was paid, are the following: Alabama, coal; Florida, phosphate rock; Georgia, coal and iron ore; North Carolina, limestone.

In addition to the contract work shown in Table 47, a large amount of such work was done at mines and quarries which did not produce any mineral in 1902, but at which development work of some kind was done. The amount paid and the number of employees engaged in contract work at idle mines or those in process of development are shown, by minerals, in the following table:

TABLE 48.—*Contract work at nonproducing mines, by minerals: 1902.*

MINERAL.	Amount paid.	Number of employees.
Total	$2,664,526	7,019
Borax	500	3
Coal, bituminous	33,767	135
Copper ore	200	1
Gold and silver	1,542,771	5,649
Iron ore	216,168	286
Lead and zinc ore	8,149	17
Manganese ore	158	1
Natural gas	104,230	173
Petroleum	758,433	753
Quicksilver	150	1

Adding the amount paid and the number of employees given in the above table to the corresponding data shown in Table 47 makes a total for the United States of $23,342,464 paid for contract work in 1902 at all classes of mines and 28,202 employees. Contract work was reported in greatest amounts from petroleum and natural-gas wells among productive properties; the largest amount of contract work at mines for which no production was reported was in the development and improvement of gold and silver mines. Petroleum and natural gas, iron ore, and bituminous coal follow in the order named.

XI.

PRODUCTION WITHOUT EMPLOYEES.

Speaking broadly, it required the services of 619,856 wage-earners and salaried employees, to whom was paid $408,980,512 to produce in 1902 the mineral product of the United States, which was valued at $796,826,417.

The conditions of mining and quarrying were such as to call for the employment of at least one person at a very large proportion of the plants, and in some branches of the industry the investment of capital in buildings and mechanical and other equipment and the organization of the working force were equal to those features of industrial organization in the largest and most important manufacturing establishments. On the other hand, in certain branches of the industry operations were conducted at many mines and quarries under conditions of the greatest simplicity with no hired labor and no mechanical equipment, with the exception of a few tools. Table 49 presents for each mineral the number of mines or quarries at which there were no employees, the proprietor doing all the work; also the value of the output of such establishments, and in adjoining columns, for purposes of comparison, the total number of mines and quarries and the value of their product with the percentage that the product of the class reporting no employees forms of the total.

TABLE 49.—*Production without employees, by minerals: 1902.*

MINERAL.	Total number of mines, quarries, and wells.	Number of mines, quarries, and wells without employees.	PRODUCT. Total value for all mines, quarries, and wells.	Value for mines, quarries, and wells without employees.	Per cent of total value.

Tungsten	4	1	5,975	234	3.9
Uranium and vanadium	3	2	48,125	5,125	10.6
All other minerals[3]	6		49,256		

[1] Less than one-tenth of 1 per cent.
[2] Includes value of product of 436 operators for whom no mines were reported.
[3] Includes mines as follows: Chrome ore, 1; magnesite, 1; molybdenum, 1; nickel and cobalt, 2; rutile, 1.

The practice of operating mines by the owner or lessee without the employment of labor is more prevalent in some mining industries than in others, and necessarily affects the relative proportion which the number of employees bears to the quantity of product for the industry considered as a whole and in its several branches. Of the total number of mines, quarries, and wells (151,516) there were only 4,368, or 2.9 per cent, at which all the work was done by the proprietors, and the value of the products of such mines, quarries, and wells was only $1,816,650, or .0.2 per cent of $796,826,417, the total for the United States for all mining industries. At the census of manufactures, of the total number of manufacturing establishments (512,254) there were 110,510, or 21.6 per cent, in which the work was done by the proprietors without hired assistance.

The industries in which there was one employee or more reported at every plant are as follows: Borax, cement, coal, anthracite; corundum and emery, crystalline quartz, feldspar, flint, fluorspar, fuller's earth, garnet, graphite, grindstones and pulpstones, lead and zinc ore, lithium ore, marl; oilstones, whetstones, and scythestones; silica sand, sulphur and pyrite, talc and soapstone, chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile.

Precious stones show the highest percentage for the value of the product obtained without employees, 21.8 per cent; this is accounted for by the fact that a value amounting to $69,550 was, as elsewhere explained, the result of accidental discoveries by individuals and not of systematic and regular mining. The other high percentages were for mica, 15.5; for uranium and vanadium, 10.6; for infusorial earth, tripoli, and pumice, 10.2; and 9.7 for asphaltum and bituminous rock. Less than one-tenth of 1 per cent of the product of bituminous coal mines was from mines without employees.

The statistics for petroleum and natural-gas wells are misleading and are not in the least representative of conditions as to the employment of wage-earners at the well. The percentage of the product of wells without employees as it appears in the table was 2 for both petroleum and natural gas. It is unquestionable that a much larger number of wells were operated and a larger output produced under conditions requiring no employees than the table indicates. The circumstances surrounding the reports of the Standard Oil Company, as previously explained, are accountable for the evident inaccuracy of the figures. Separate reports were not furnished by this company for the different groups of wells under its ownership or control, or for the wells in different counties, but the reports were made by states, the report for a state including all oil or gas operations in that state; it was, therefore, obviously impossible to determine from the reports whether or not particular wells or groups of wells required hired labor for their operation.

XII.

IRREGULAR PRODUCERS.

A large proportion of the mining and quarrying done in this country is of a regular and stable character, and there was no great difficulty encountered in securing complete Census reports from most of the operators of this class. There are, however, in some branches of mining and quarrying irregular producers who operate independently, working at such times as they feel inclined or only enough to obtain a product sufficient to satisfy the local demand. Some of these small operators work the same digging from time to time, while others, such as the placer gold and monazite miners, work in different localities, selected with reference to the richness of the deposits. It was found to be impossible to

secure Census reports from all operators of this class, but the necessary information was sometimes obtained from merchants who purchased the products, or from others.

This condition was exemplified in the monazite industry of North Carolina. The industry is one of placer mining, and is carried on in many instances irregularly by men whose expenses are sometimes advanced by the operators of a concentrating plant, who purchase their production, and from whom—as it was found impossible to obtain reports from the miners themselves—the report was obtained covering the operations of all. The men thus irregularly engaged in monazite mining are not employees or wage-earners, strictly speaking, but it was considered that they should be so treated in the statistics. Several hundred were reported as so employed, but by the method of reduction to the average for the entire year this number was very greatly reduced. The amount paid for the crude monazite at the concentrator was treated as the wages of these miners.

Somewhat similar conditions existed in the manner in which the operations were conducted in placer mining for gold. The mines were quite generally found in localities remote from settled communities and difficult to reach on that account, and partly for this reason the special agents engaged in making the canvass were instructed not to secure reports from placer mines at which less than two wage-earners were employed. This has resulted in the omission from the statistics of about one-fourth of the placer mines. Unlike the method followed in the treatment of statistics of monazite, no cognizance has been taken in the statistics, either by estimate or otherwise, of the operations thus omitted.

Again, in 1902, a large proportion of the output of precious stones was the result of work that was not open to statistical treatment as to capital, employees and wages, expenses, etc. The entire value of this product for the United States was $328,450, of which $69,550, or 21.2 per cent, was the value of different varieties of precious stones that were yielded not by systematic mining operations, but by accidental discovery here and there in the search for other minerals. For this part of the production, therefore, statistics for value of product alone are presented.

In bituminous coal mining there was a large number of mines which are classed as "local" mines or "farmers' coal banks," which were operated only to supply the needs of the neighborhood in which they were located. The number of such mines as reported at the Eleventh Census was 9,969, as compared with 826 reported at the census of 1902. The difference in the numbers reported at the two censuses is due largely, if not entirely, to the failure to reach all of these unimportant mines in 1902. According to the returns received from such mines, wage-earners were employed to but a limited extent and only for short periods, and when the total number was reduced to an average for the year, the result was a very insignificant number as compared with the total number of wage-earners employed in the industry.

XIII.

TIME IN OPERATION.

Table 50 shows the number of mines, quarries, and wells classified according to time in operation by periods of thirty days, by the number of shifts per day, and by the number of hours in a shift, from six to twelve. The number of mines for which the information was not reported also appears.

TABLE 50.—TIME IN OPERATION: 1902.

[1] Duplication of 33 mines which reported more than one class of shifts per day, distributed as follows: Colorado, 13; California, 11; Idaho, 3; Oregon, 3; South Dakota, 1; Texas, 1; Utah, 1.

[2] Duplication of 34 mines which reported more than one number of "hours per shift," distributed as follows: Colorado, 4; California, 20; Idaho, 3; Montana, 1; Nevada, 1; Oregon, 4; Texas, 1.

[3] Includes mines as follows: Chrome ore, 1; magnesite, 1; molybdenum, 1; nickel and cobalt, 2; rutile, 1.

At many of the mines and quarries work was extremely irregular on account of fluctuating demands and the interruption of operations by seasonal changes.

From the totals for all minerals it appears that a large majority of the mines, quarries, and wells in the United States worked full time throughout the year, or from 301 to 365 days, with two shifts of 12 hours each per day; but this is caused by the fact that nearly all of the natural-gas and petroleum wells were in constant operation both day and night for periods exceeding 300 days. If the statistics for these wells are omitted, it will be seen that one shift of 10 hours was the most general plan, with the 8-hour day next in importance.

When the figures for petroleum and natural-gas wells are deducted from the totals for all minerals a total of 17,039 mines and quarries is obtained; of this number 14,339 worked one shift, 1,136 worked two shifts, 206 were operated by three shifts, and for 1,391 the information was not reported. The shift was 10 hours in length at 8,422 mines, 8 hours at 4,375, 9 hours at 2,463, and 12 hours at 254, and for 1,367 the information was not reported.

The larger number of anthracite coal mines were in operation from 91 to 210 days. This comparatively short period of operation was, as elsewhere explained, due to a strike in that industry. Of the total number of mines, 328 were operated by only one shift per day, which appeared to be the rule; the length of the shift was quite generally 10 hours.

The bituminous coal mines seem to be quite evenly distributed as to the number of days in operation, a large number appearing in each group from 30 days and less in those which exceeded 300 days. The larger number, however (3,133), were reported as operating for periods from 181 days to 300 days. One shift of 8 hours appears to have been the general custom.

In copper mining the mines working two shifts were more numerous than those working one, and a considerable proportion of gold and silver and iron ore mines worked more than one shift per day.

The statistics show that a very large proportion of

natural-gas and petroleum wells were in operation from 301 to 365 days, working two shifts of 12 hours each per day.

The stone quarries, including marble, limestones and dolomites, sandstones and quartzites, siliceous crystalline rocks, and slate, according to the table, with comparatively few exceptions, worked but one shift per day. The larger proportion were reported as working 10 hours per shift, although a considerable number reported 8 and 9 hour shifts.

XIV.

MISCELLANEOUS EXPENSES.

An inquiry concerning miscellaneous expenses was first included in the schedules at the census of 1890, when the "total of all other expenditures in the mines or works (including amounts paid for rent, taxes, insurance, interest, etc.)" was reported as a separate item. The same inquiry at the census of 1902 required separate amounts to be reported for (1) royalties and rent of mine and mining plant, and (2) amount paid for rent of office, taxes, insurance, interest, advertising, office supplies, law expenses, injuries and damages, telegraph and telephone service, gas, and all other sundries not reported elsewhere. In the special schedule for gold, silver, lead, and copper mines, these amounts were further itemized as follows: (1) Amount expended in development work; (2) rent and royalties of mine and mineral land; (3) rent of mining plant and improvements; (4) rent or royalty for tunnel privileges; (5) water rent; (6) other rent or royalties; (7) amount paid for taxes, insurance, interest, advertising, office supplies, law expenses, injuries and damages, telegraph and telephone service, gas, and all other sundries not reported elsewhere.

Of the total amount paid as miscellaneous expenses, $47,805,681, or 66.6 per cent, was reported by mine operators engaged in the production of fuels, and $17,168,321, or 23.9 per cent, for the metallic group, leaving only $6,797,711, or 9.5 per cent, for all other minerals.

The amounts reported in answer to the several inquiries are shown in detail in the reports for the different minerals. The miscellaneous expenses reported for all minerals amounted to $71,771,713, of which sum $34,530,713, or 48.1 per cent, was paid as royalties and rent of mines and mining plants. Royalties and rent form the most important single item included in the group of miscellaneous expenses, and, with the exception of salaries, wages, and supplies and materials, is the most important item of expenditure reported for mining operations. Of the total ($625,245,130) reported as expenses—salaries and wages amounted to $408,980,512, or 65.4 per cent; supplies and materials to $123,814,967, or 19.8 per cent; miscellaneous expenses to $71,771,713, or 11.5 per cent; and contract work to $20,677,938, or 3.3 per cent. Table 51 shows the amount of miscellaneous expenses reported for the different groups of minerals and the percentage that the totals for each group are of the total for all minerals.

TABLE 51.—*Miscellaneous expenses, by groups of minerals and percentage each group is of total: 1902.*

GROUP.	TOTAL.		ROYALTIES AND RENT OF MINE AND MINING PLANT.		RENT OF OFFICES, TAXES, INSURANCE, ETC.	
	Amount.	Per cent.	Amount.	Per cent.	Amount.	Per cent.
All minerals	$71,771,713	100.0	$34,530,713	100.0	$37,241,000	100.0
Metallic	17,168,321	23.9	9,591,964	27.8	7,576,357	20.3

Miscellaneous	202,801	0.3	67,693	0.2	135,108	0.4

[1] Less than one-tenth of 1 per cent.

No analysis is possible of the amounts paid for rent of offices, taxes, insurance, etc., although these expenditures form the larger proportion of the miscellaneous expenses reported for a number of the minerals.

Royalties and rent.—Payments for the use of mineral lands are either in the form of a rental of a fixed amount or are made as percentages of the quantity of mineral extracted or of the value of the metal recovered. The importance of royalties and rent is indicated by the fact that in the total for all minerals it forms 4.3 per cent of the value of the products; in the metallic group, 4.5 per cent; in the fuels, 5 per cent; and in the other groups of minerals from seven-tenths of 1 per cent to 7.2 per cent of the value of the products. The largest amounts are paid as royalties and rent in the production of fuels, the expenditure forming an important item of the total cost. In the production of coal the royalty is usually specified in the contracts with the landowners and is generally a certain rate per ton of coal raised. The variation in the amount of royalty paid per ton in the production of anthracite coal is shown in the following table, which gives the number of operators paying each rate:

TABLE 52.—*Coal, anthracite—number of operators at various rates of royalty: 1902.*

13.0	1	29.0	2		
14.9	1	30.0	13		

Of the 119 operators reporting for the production of anthracite coal, 84 reported the payment of royalties varying from three-tenths of 1 cent to 60 cents per ton. The most common rates of royalty were 5 cents per ton and multiples of that amount; 14 operators reported royalty payments of 5 cents per ton; 16, of 10 cents; 9, of 15 cents; 12, of 20 cents; 20, of 25 cents; 13, of 30 cents; 18, of 35 cents; and 10, of 40 cents. A number of mine operators reported different rates of royalty, each depending upon the terms of the contract with the individual owning the land. As large quantities of coal are mined from land owned by the operators, the amount of royalty paid has no relation to the value of the product reported for all mines.

The following table shows the number of bituminous coal operators reporting royalties at the rates specified:

TABLE 53.—COAL, BITUMINOUS—NUMBER OF OPERATORS IN EACH STATE AT VARIOUS RATES OF ROYALTY: 1902.

[1] Includes operators distributed as follows: Alabama, 49; Arkansas, 25; California, 1; Indian Territory, 31; Maryland, 17; Michigan, 28; Montana, 4; New Mexico, 7; North Dakota, 6; Oregon, 4; Tennessee, 38; Texas, 9; Utah, 3; Virginia, 17; Washington, 10; Wyoming, 9.

Of the 4,409 operators engaged in the production of bituminous coal, 2,130, or 48.3 per cent, reported the payment of royalties varying from eight-tenths of 1 cent to $1.50 per ton. The rates most commonly reported were from 5 to 15 cents per ton, there being 1,850 operators paying royalties coming within these amounts.

The amount paid as royalties and rent in the production of petroleum was reported as $8,929,891, being one-eighth of the value of the product. In the majority of instances the royalty was a percentage of the oil produced. This percentage ranged from a fraction of 1 per cent to 50 per cent, but the usual amount of petroleum paid to the landowners was one-eighth of the amount marketed or sold to the pipe line companies. In a few cases a fixed amount was paid for each barrel. In northern Pennsylvania and southeastern Ohio a comparatively small amount of superior petroleum was produced, for which the operators paid one-sixth. Part of the petroleum produced in Kansas and Texas, and practically all of that produced in California, paid one-tenth.

The manner in which the amount of royalty to be paid is determined and the method of payment is

described by Mr. F. H. Oliphant, in the United States Geological Survey monograph, "The Production of Petroleum," 1902, pages 41 and 42.[1]

In the production of natural gas $2,533,895 was reported as rent and royalties. The usual rent paid for a gas well was from $100 to $300 per year.[2]

[1] The pipe line company, upon application from the producer, sends an agent, generally known as a "gauger," to measure and inspect the petroleum in his tank and run it into its lines, the tanks throughout the field having been carefully measured and a card issued showing the number of barrels from top to bottom to each inch of liquid. From his blank book the gauger gives the operator a "run ticket," sending a duplicate to the nearest general office as well as reporting the amount by telegraph, keeping a third one himself. The pipe line company deducts the amount due the owner of the property according to the terms of an agreement on file at the office, known as the royalty, and the next day the producer can secure the cash for his petroleum at the market quotation for the day or hour of his sale, at the nearest home office of the company, from a purchaser for the refining companies; or, if the producer wishes, he can obtain a certificate when his production in the tanks of the pipe line company amounts to 1,000 barrels.

These certificates are made payable to bearer, and are therefore transferable. They are subject to a transportation charge in the district of 20 cents per barrel and a charge for storage at the rate of 25 cents per day per 1,000 barrels when the price is less than $1, 30 cents when over $1 and under $1.50, and 40 cents for all over $1.50 per barrel. They are to be returned for exchange to the pipe line company within six months after issue, or be subject to a charge of one-twentieth of 1 per cent daily thereafter until exchanged. To cover losses by fire or lightning certificates are subject to an assessment pro rata on all oil in the custody of the pipe line. None of these charges are included in the prices of petroleum as quoted, and therefore the prices given are the prices at or near the wells. This system, by which the operator can always find a market for his production at a common price known to all, has done much to develop the oil resources of the United States. Other countries have suffered where there were no organized lines of transportation and storage to enable the producer to dispose of his products regularly.

[2] The form of lease for petroleum and gas wells is generally as follows:

Agreement made and entered into the —— day of ——, A. D. 190—, by and between ——, of ——, county of —— and state of ——, part—— of the first part, and —— part—— of the second part.

Witnesseth, That the said part—— of the first part, for and in consideration of the sum of one dollar to —— in hand well and truly paid by the said part—— of the second part, the receipt of which is hereby acknowledged, and of the covenants and agreements hereinafter contained on the part of the said party of the second part, to be paid, kept, and performed, ha—— granted, demised, leased, and let and by these presents do —— grant, demise, lease, and let unto the said part—— of the second part, —— heirs, executors, administrators, or assigns, for the sole and only purposes of mining and operating for oil and gas, and of laying pipe lines, and of building tanks, stations, and structures thereon to take care of the said products, all that certain tract of land, situate in —— township, —— county, and state of ——, on waters of ——, bounded substantially as follows: On the north by lands of ——; on the east by lands of ——; on the south by lands of ——; on the west by lands of ——; containing —— acres, more or less, and being same land conveyed to the first part—— by —— by deed, bearing date ——, 18—, reserving, however, therefrom —— feet around the buildings on which no well shall be drilled by either party except by mutual consent.

It is agreed that this lease shall remain in force for the term of ten years from this date, and as long thereafter as oil or gas or either of them is produced therefrom by the party of the second part, —— heirs, executors, administrators, or assigns.

In consideration of the premises the said part—— of the second part covenants and agrees: First. To deliver to the credit of the first part——, —— heirs or assigns, free of cost, in the pipe line to which it may connect its wells, the equal one-eighth part of all oil produced and saved from the leased premises; and, second, to pay 100 to 300 dollars per year for the gas from each and every gas well drilled on said premises, the product from which is marketed and used off the premises, said payment to be made on each well within sixty days after commencing to use the gas therefrom, as aforesaid, and to be paid yearly thereafter while the gas from said well is so used.

Second part—— covenant— and agree— to locate all wells so as to interfere as little as possible with the cultivated portions of the farm. And further, to commence a well on said premises within —— from the date hereof, or pay at the rate of —— dollars quarterly, in advance, for each additional three months such commencement is delayed from the time above mentioned for the commencement of such well until a well is commenced; and it is agreed that the commencement of such well shall be and operate as a full liquidation of all rental under this provision during the remainder of the term of this lease. Such payments may be made direct to the lessor— or deposited to —— credit in ——.

It is agreed that the second party is to have the privilege of using sufficient water from the premises to run all necessary machinery, and at any time to remove all machinery and fixtures placed on said premises; and, further, upon the payment of —— dollars at any time by the party of the second part, —— heirs, executors, administrators, or assigns to the part—— of the first part, —— heirs, executors, administrators, or assigns, said party of the second part, —— heirs, executors, administrators, or assigns shall have the right to surrender this lease for cancellation, after which all payments and liabilities thereafter to accrue under and by virtue of its terms shall cease and determine, and this lease become absolutely null and void.

In witness whereof the parties to this agreement have hereunto set their hands and seals the day and year first above written.

The following statement shows the amount of royalties and rent paid in the production of natural gas and petroleum in each state and the percentages the amounts so paid bear to the value of the product for the states and for the United States:

STATE.	NATURAL GAS.		PETROLEUM.	
	Amount paid for royalties and rent of mine and mining plant.	Per cent of value of product.	Amount paid for royalties and rent of mine and mining plant.	Per cent of value of product.
United States	$2,533,895	8.2	$8,929,891	12.5
California			214,261	4.4
Colorado			18,597	3.8
Indiana	539,844	7.6	1,034,070	15.8
Kansas	21,038	2.6	28,255	9.7
Kentucky	8,725	2.4	53,613	31.0
New York	32,439	9.4	194,717	12.7
Ohio	198,671	8.4	3,046,994	14.7
Pennsylvania	1,223,278	8.5	1,916,987	12.6
Texas	2,032	13.6	261,150	6.3
West Virginia	507,868	9.4	2,132,243	12.5
All other states and territories[1]			29,004	10.4

[1] Includes Illinois (no royalties paid), Indian Territory, Louisiana, Michigan, Missouri, Oklahoma, Tennessee, and Wyoming.

In the group of metallic ores the largest amount was paid in royalties in the production of iron ore, the total, $6,503,908, paid in this branch of mining forming 67.8 per cent of the $9,591,964 reported for the entire metallic group.

The following statement shows the amounts paid as royalties and rent in the iron mines in the different states and the percentage that total is of the total for the United States:

STATE.	Amount paid for royalties and rent of mine and mining plant.	Per cent of total.
United States	$6,503,908	100.0
Alabama	37,938	0.6
Colorado	87,094	1.3
Georgia	8,351	0.1
Maryland	2,271	[1]
Michigan	2,254,864	34.7
Minnesota	3,648,750	56.1
Missouri	2,538	[1]
New Jersey	7,915	0.1
New York	12,385	0.2
Ohio	1,503	[1]
Pennsylvania	26,343	0.4
Tennessee	93,672	1.5
Virginia	93,429	1.5
Wisconsin	181,243	2.8
All other states and territories	45,612	0.7

[1] Less than one-tenth of 1 per cent.

The operators in the states of Michigan and Minnesota paid $5,903,614 in royalties and rent, or 90.8 per cent of the total amount paid in the United States. Of the 72 operators reported for these states, 61 paid either rent or royalty. The state of Minnesota has adopted a system of leasing its iron lands for a term of years to prospectors and miners, and a royalty of 25 cents per ton is imposed on all iron ore mined and shipped from state lands. The state has received $332,119.02 in royalties on iron ore actually shipped up to the end of the fiscal year, July 31, 1902, and by annual payments on mining contracts, payment for prospecting leases, and

as royalty on a minimum output of 5,000 tons per year, the further sum of $212,515.75 has been turned into the state treasury, making a total of $544,634.77.[1]

Zinc mining lands are seldom sold, but are usually worked on royalties. Lands which have never been prospected are leased on a percentage royalty. The lessee prospects the land and lots are then subleased to mine operators at a larger percentage royalty than is paid by the first lessee. The first lessee usually contracts to put in pumping plants and keep the tract drained. The ore is sold in the bins and payment is made to the landowner or first lessee, who deducts his royalty and pays over the balance to the operator. Very frequently the sublessee further leases small plots to miners, usually neighboring farmers, who undertake to work the land on a royalty. The larger land companies buy all ore produced by these miners at a stipulated price, deducting from it the royalty. In such cases the terms resemble contract mining as practiced in other branches of the mining industry. The total amount of royalties reported for zinc mines at the Twelfth Census was $1,525,368. The royalty is computed on the price paid by the purchaser for ore in the bins; if the ore sells at $30 per ton and the royalty is 20 per cent, the landowner deducts $6 per ton for his royalty and draws his check for $24 to the operator.

Mining on royalties is of little importance in the copper mining industry. The total amount of royalties and rents paid in 1902 was $130,215, of which only $33,184 represented royalties. This was about 25 per cent of the gross value of the ore upon which the royalties were paid. Considering that the total production of copper ore was valued at $51,178,036 at the mine, it is apparent that royalties can not be considered a factor in copper mining.

In gold and silver mines the royalty is usually stipulated at a certain percentage of the net value realized for the ore, after deducting treatment charges and freight; the rate increases with the grade of the ore. Thus if the ore is worth $20 per ton, the cost of treatment and freight is $10, and the rate of royalty is 25 per cent; then the landowner is paid $2.50 per ton, which leaves $7.50 for the operator. Sometimes, though seldom, the rate is stipulated upon the gross value—say 10 per cent of the assay value of the ore; taking the same figures as in the preceding example, the royalty would amount to $2, which would leave for the operator $18, from which $10 would be deducted for treatment and freight, leaving a net balance of $8 for the operator.

In Colorado, where the mines are often leased in "blocks" to miners who perform the labor personally, the ore is marketed by the owner or shipped in his name, and he deducts his royalty and pays the balance to the lessee. When the ore is sold to a "sampler" (ore buyer), he frequently withholds the royalty for the owner and pays the balance to the lessee.

[1] Report of the auditor of the state of Minnesota for the fiscal year ending July 31, 1902.

XV.

COST OF SUPPLIES AND MATERIALS.

The cost of supplies and materials of all kinds used in the mining industries during the year, including freight on the same when paid by the mine operator, amounted to $123,814,967. This includes lumber and timber used for repairs, mine supports, track ties, cars, and other purposes; iron and steel for blacksmithing, rails, frogs, sleepers, etc., for tracks; miscellaneous materials, parts of machinery, and tools used for renewals and repairs; and also explosives, water for boilers and other purposes, fuel, illuminating and lubricating oils, machinery, supplies, etc. Supplies may have been purchased with the intention of taking advantage of low prices, but only the cost of those used during the year was reported. The "material" operated upon in a mine is the mineral in place, and its cost is included in the cost of the land or in the amounts paid for royalty and rent. All the items here enumerated come under the definition of "supplies," and the total cost may be accepted as representing the purchase of supplies, with the exception of the purchase of lime rock by quarry companies engaged in the manufacture of cement. The totals are summarized in Table 54 and placed in comparison with the value of product for each mineral and group of minerals.

TABLE 54.—COST OF SUPPLIES AND MATERIALS, AND PERCENTAGE THIS IS OF VALUE OF PRODUCT, BY MINERALS AND GROUPS OF MINERALS: 1902.

MINERALS, BY GROUPS.	Cost of supplies and materials.	Value of product.	Percentage that cost of supplies and materials is of value of product.
Total	$123,814,967	$796,826,417	15.5
Metallic	39,639,703	215,453,587	18.4
Copper ore	11,083,175	51,178,036	21.7

Gypsum	341,760	2,089,341	16.4
Phosphate rock	799,414	4,922,943	16.2
Sulphur and pyrite	217,262	947,089	22.9
Pigments	65,845	564,039	11.7
Barytes	7,772	203,154	3.8
Mineral pigments, crude	58,073	360,885	16.1
Miscellaneous	424,894	3,344,181	12.7
Asbestos	8,233	46,200	17.8
Asphaltum and bituminous rock	21,928	236,728	9.3
Bauxite	40,019	128,206	31.2
Feldspar	50,278	250,424	20.1
Flint	18,642	144,209	12.9
Fuller's earth	28,966	98,144	29.5
Graphite	51,840	227,508	22.8
Lithium ore	1,265	25,750	4.9
Marl	2,755	12,741	21.6
Mica	11,961	118,849	10.1
Monazite	256	64,160	0.4
Precious stones	17,781	328,450	5.4
Silica sand	38,386	421,289	9.1
Talc and soapstone	125,932	1,138,167	11.1
Tungsten	210	5,975	3.5
Uranium and vanadium	3,010	48,125	6.3
All other minerals	3,432	49,256	7.0

The various conditions under which mining operations are carried on destroy the possibility of a fixed ratio between the cost of supplies and the value of product for any mineral or group of minerals; therefore the percentages given in the above table should not be accepted as indicating such a ratio. They show only the relative importance of this item of expense for all mines, irrespective of the conditions under which they were operated. The total amount paid for supplies and materials for the entire mining industry was 15.5 per cent of the total value of product. The percentages that cost of supplies and materials formed of the value of the product ranged from 0.4 per cent for monazite to 37.5 per cent for cement. The high proportional cost in the latter was due in part to the fact that some crude cement rock was purchased from quarries that were not equipped for manufacturing cement, and large amounts were paid for cooperage stock, barrels, and other packages in which the product was packed for shipment.

XVI.

POWER AND MACHINERY.

The use of power is becoming more general in all branches of productive industry. In the mining industries power is employed for a variety of purposes, the chief of which are the operation of hoisting, draining, ventilating, conveying, drilling, and cutting machinery, derricks, steam shovels, and locomotives and hauling engines. It is also employed extensively in the operation of machinery used in crushing, screening, cleaning, or otherwise treating the crude material. Motive power is now generally used in all mining operations of any magnitude.

Table 55 shows the number of operators reporting the use of power and the value of their products in comparison with the total number and value of products for all operators for each classification and group of minerals.

TABLE 55.—NUMBER OF OPERATORS REPORTING USE OF POWER AND THE VALUE OF THEIR PRODUCTS COMPARED WITH TOTALS FOR ALL OPERATORS, BY MINERALS AND GROUPS OF MINERALS: 1902.

MINERALS, BY GROUPS.	NUMBER OF OPERATORS.			VALUE OF PRODUCT.		
	Total.	Reporting use of power.	Per cent which number reporting use of power forms of total number.	Total.	For operators reporting use of power.	Per cent which value of product for operators reporting use of power forms of total value.
All minerals	46,858	35,943	76.7	$796,826,417	$732,324,376	91.9
Metallic	4,081	2,058	50.4	215,453,587	204,828,082	95.1

Uranium and vanadium	3			48,125		
All other minerals [3]	6	2	33.3	49,256	20,889	42.4

[1] Includes 28,925 operators reported by the Standard Oil Company, for which statistics of power were reported collectively.
[2] Less than one-tenth of 1 per cent.
[3] Includes chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile.

Of the 46,858 operators reported for all classes of minerals, 35,943, or 76.7 per cent, reported the use of power. The value of the products reported by operators using power amounted to $732,324,376, or 91.9 per cent, of the total value of products for all operators. In other words, all but 8.1 per cent of the mineral products of the country were obtained by operators who reported the use of power to some extent.

The entire production of anthracite coal, borax, fuller's earth, magnesite, and rutile was obtained by operators using power. For ten of the different classifications of minerals enumerated in the above table the use of power was reported by operators producing more than 95, but less than 100 per cent of the value of product. Of the seven groups of minerals the metallic group shows the largest proportion, 95.1 per cent, for the products obtained by operators using power. The next largest proportion, 91.9 per cent, is shown for the group of fuels, while for the remaining groups the percentages of the products obtained by the use of power are as follows: 91.2 per cent for chemical materials, 86.2 per cent for structural materials, 72.5 per cent for miscellaneous materials, 49.8 per cent for pigments, and 48 per cent for abrasive materials. The table shows very conclusively that practically all of the large producers employed mechanical power in some form.

In compiling these statistics, steam, gas or gasoline, and water were considered as primary power, and rented power of all classes was included under the same head. Gas engines embrace all forms of internal combustion engines in which the propelling force is the explosion of gaseous or vaporous fluid in direct contact with a piston within a closed cylinder. The inquiry concerning mechanical power called for a full report of all power employed, either owned or rented, including the number and horsepower of all engines, motors, water wheels, etc., used for ventilating, pumping, hoisting, derricks, surface machinery, and all other purposes. The power reported in answer to this inquiry amounted to 2,867,562 horsepower for all branches of mining. Of this total, 2,432,963 horsepower, or 84.9 per cent, was steampower; 60,897 horsepower, or 2.1 per cent, was waterpower; and 373,702 horsepower, or 13 per cent, was obtained from other forms of mechanical power, including electricity, gas engines, air compressors, etc. The use of steampower largely predominated in mining operations, other forms of primary power in comparison having only a limited application. While inquiries concerning power were included in the schedules used at previous censuses, they do not appear to have been answered uniformly, and the comparisons can not be accepted as an accurate indication of the increase in the quantity of power employed. The following table, however, presents the total horsepower reported at the censuses from 1870 to 1902:

TABLE 56.—*Horsepower: 1870 to 1902.*

MINERAL.	TOTAL HORSEPOWER.			
	1902	1889 [1]	1880	1870

[1] Horsepower of boilers reported.
[2] Not reported.
[3] Exclusive of waterpower used at arrastra mills, and all power at stamp and amalgamating mills.
[4] Reported for eastern and southern zinc mines only.
[5] Reported for mines east of the one-hundredth meridian.
[6] Includes all stone except marble and slate.
[7] Included with limestones and dolomites.

Since statistics for power were not reported in a uniform manner at these censuses, the totals for the United States are not shown in Table 56. The figures can be accepted only as an indication of the more general use of power in mining operations and not as a basis for computing the actual increase in the horsepower employed in the industry. The inquiry for 1902 was confined to the operation of mines, quarries, or wells and such manufacturing processes as were carried on in immediate connection therewith. A number of minerals for which power was reported at the census of 1902 were not produced in commercial quantities at one or more of the three preceding censuses, or if they were so produced, power was not reported as employed in the mining operations.

The detailed statistics for the different varieties of

power reported for each mineral, each group of minerals, and for all minerals in each state are shown in Tables 1 and 2, pages 347 to 377. The following table shows the number of operators in each class of minerals and group of minerals reporting the use of the different varieties of power, and the total amount of horsepower employed:

TABLE 57.—NUMBER OF OPERATORS REPORTING THE USE OF THE DIFFERENT KINDS OF POWER, AND TOTAL HORSEPOWER: 1902.

MINERALS, BY GROUPS.	OPERATORS.		Total horsepower.	STEAM ENGINES.		GAS OR GASOLINE ENGINES.		WATER WHEELS.		ALL OTHER POWER.

[1] Includes 28,925 operators reported by the Standard Oil Company for which statistics of power were reported collectively. A large number of operators, therefore, are duplicated in steampower and gas or gasoline power.

[2] Includes chrome ore, lithium ore, molybdenum, and nickel and cobalt.

All the operators reported for five of the minerals enumerated in the above table used mechanical power. The number of operators reported for the remaining minerals for which power was used includes all the operators of small mines and quarries, a number of whom work at irregular intervals, and the small lessees; therefore the comparison of the number of operators reporting the use of power, with the total number reported for each mineral, does not convey a correct impression of the importance of motive power in the

mining industries of the country. The following statement shows the proportion of each variety of power employed in the production of the different groups of minerals:

Per cent of each kind of power employed in the different groups of minerals: 1902.

GROUP.	OPERATORS.		Total horsepower.	POWER.							
	Total number.	Number reporting power.		Steam engines.		Gas or gasoline engines.		Water wheels.		All other power.	
				Number of operators.	Horsepower.	Number of operators.	Horsepower.	Number of operators.	Horsepower.	Number of operators.	Horsepower.

Miscellaneous	1.5	0.3	0.4	0.2	0.3	(1)	0.1	4.0	6.0	0.4	0.1

[1] Less than one-tenth of 1 per cent.

Of the total power for all minerals, including natural gas and petroleum, 1,969,569 horsepower, or 68.7 per cent, was reported by the operators engaged in the production of fuels. The universal use of power in anthracite coal mining, its very general application in the production of bituminous coal, and its use in the necessary pumping machinery at petroleum wells account for the large amount of power reported for the operators included in this group.

The metallic group, with 557,933 horsepower, or 19.4 per cent of the total, is the second in importance in the quantity of power used. While the operators in this group formed a comparatively small proportion, (5.7 per cent) of the total number of operators reporting the use of power, they produced a very large proportion of the total product. The fact that a large number of small operators reported for gold and silver and bituminous coal used no motive power is the principal reason for the small proportion using power.

While the use of power was an important factor in the production of practically all of the minerals, the horsepower reported for structural materials, abrasive materials, chemical materials, pigments, and miscellaneous minerals formed only 11.9 per cent of the total.

The following statement shows the proportion of steam, gas, water, and other power employed in the production of each group of minerals:

Per cent of operators reporting power, and per cent of these reporting steam, gas, water, or other power, by groups of minerals: 1902.

GROUP.	Per cent of operators reporting power.	POWER.			
		Steam, per cent of total.	Gas or gasoline, per cent of total.	Water, per cent of total.	All other, per cent of total.
All minerals	76.7	84.8	9.1	2.1	4.0
Metallic	50.6	81.6	1.0	8.2	9.2
Fuels	87.6	84.6	12.6	0.1	2.7
Structural materials	35.5	92.6	1.4	2.9	3.1
Abrasive materials	38.7	92.2	3.5	.....	4.3
Chemical materials	73.6	93.6	1.0	3.8	1.6
Pigments	29.9	67.2	2.0	28.2	2.6
Miscellaneous	14.8	65.4	1.6	32.2	0.8

There were 35,060 operators, including those for natural gas and petroleum, that reported the use of steampower. This class of power predominated in each of the general groups of minerals and formed 84.8 per cent of the power reported for all mining operations. The use of gas or gasoline engines was reported by 29,530 operators, the horsepower amounting to 259,695, or 9.1 per cent of the total. Engines of this variety predominated in the fuel industries as a result of the free use of natural gas and petroleum for motive power at the wells. The reports showed that 980 water wheels, with 60,897 horsepower, were used by 471 operators, and of this total 43,936 horsepower, or 72.1 per cent, was employed in the production of gold and silver.

The 84,546 horsepower reported for other kinds of power is composed very largely of the horsepower of air compressors.

A number of the mine operators reported that power was supplied by them to other mines or to operators engaged in other industries, there being 2,852 horsepower rented in this manner. A number also reported that they rented power from other operators or power companies, the rented power amounting to 29,461 horsepower, 23,556 of which was electric. The electric power generated by the mine operators amounted to 130,494 horsepower, which, with the electric power rented, makes a total of 154,050 electric horsepower used in the mining industry.

Under the present methods of operation mechanical power for hoisting, ventilating, and pumping is indispensable in mining operations of magnitude. Special inquiries were included in the schedules for gold, silver, and copper mines, concerning the character of power used in the operation of hoisting and pumping engines, and the following statement shows the number of engines employed for this purpose and operated by each class of power.

Number of hoisting and pumping engines employed in gold and silver and copper mining: 1902.

POWER.	GOLD AND SILVER.		COPPER.	
	Hoisting engines.	Pumping engines.	Hoisting engines.	Pumping engines.
Total	1,249	840	228	160
Steam	968	663	158	153
Gas or gasoline	84	21	16	2
Compressed air	91	84	51	2
Water	50	30	.....	2
Electric	56	42	3	1

In addition to the foregoing power the gold and silver and copper mines reported 3,399 power drills. Of these 302 were driven by steam, 3,060 by compressed air, 4 by water, and 33 by electric power. The gold and silver mines used also 32 steam shovels or derricks, and 44 dredges. Forty-nine locomotives also were reported for this industry.

While a perfect system of ventilation is of prime importance in all deep mines, the schedule for coal mines was the only one that contained inquiries on this subject. Of the 334 mines producing anthracite coal, reports for 271 showed the use of fan ventilators and 1 the use of exhaust steam. The remaining 62 reports either contained no answer to the inquiry or the statement was made that no mechanical arrangements were used. Of the reports for the 5,652 bituminous coal mines, 4,844 contained answers to these inquiries, showing that at 2,215, fan ventilators were used; at 1,355, furnaces; at 91, fire baskets; at 70, exhaust steam; while for 1,112 it was reported that ventilation was accomplished without the use of mechanical arrangements.

Mechanical systems of haulage were reported as in use in 201 anthracite mines. In 52 the tail rope was used; in 13, the endless rope; in 27, electric locomotives; and in 28, compressed air; while for 81 miscellaneous systems were reported. In the bituminous coal industry 502 mines used the tail rope; 105, the endless rope; 340, electric locomotives; 19, compressed air; and 65, other systems. In addition to other machinery, automatic slate pickers and coal cleaners were reported as in use at 258 anthracite coal mines.

A brief description is given in the following list of the most important mining machinery operated by motive power:

POWER DRIVEN MINING AND ORE DRESSING MACHINERY.

Air compressor: A machine for compressing air for use as a motive power in mines and quarries and for ventilation in shafts or mines. It may be direct steam driven, or driven from line shaft, electric motor, water wheel, or gas engine, by belt, rope, gearing, or silent chain.

Air drill: See Drill.

Amalgamating pan: A machine for grinding and amalgamating ore. It consists of a flat-bottomed iron pan, about 5 feet in diameter and from 2½ to 3½ feet deep, with an iron cone in the center, and sides nearly or quite vertical. In it a horizontal, annular disk, called a muller, is revolved.

Arrastra or drag-stone mill: A form of apparatus for comminuting gold and silver ores. The name is derived from the Spanish word meaning "to drag," and is indicative of the principle of the apparatus. It consists of a circular pavement from 6 to 20 feet in diameter, with a retaining wall from 2 to 4 feet high around it, made as nearly as possible impervious to water or quicksilver. In the center is a vertical rotating post, to whose radial arms are attached blocks of stone or mullers, which are dragged over the ore in the inclosure, thus crushing it.

Ball grinder: A pulverizer for minerals. It depends upon the attrition of spheres rolling inside a rotating cylinder, the periphery of which is provided with a cast steel ring, perforated with small holes. The heads of the cylinder are of heavy cast iron, lined with steel. It contains several steel balls from 2 to 5 inches in diameter. The steel ring is the crushing plate upon which the balls break up the material to a size varying from a powder to the size of the holes in the ring. In some cases a single large ball is used, moving in a grooved path.

Boring machine: See Drill; Hydraulic boring machine, etc.

Breaker: A machine for reducing ore as it comes from the mine to an approximately uniform size convenient for further working. In jaw crushers the ore is broken between a stationary and a movable jaw. Gyratory crushers, often called "coffee mill" crushers, are in part an application on a large scale of the principle of the ordinary household coffee mill. See also Coal breaker; Roll crusher; Ball grinder; Stamp mill, etc.

Buddle: One of that class of concentrating machines depending upon the principle of the settling of minerals in the order of their specific gravities. In round buddles the tables are convex-conical or concave-conical. In the stationary buddle the pulp is fed from slowly revolving feed pipes running from a main pipe in the center, and discharging at the circumference of the table, if an inward-flow buddle; or from a slowly revolving central feed, if an outward-flow buddle. In the revolving buddle the table revolves, while the feed is stationary. Distributing brushes spread the deposits evenly over the surface of the table.

Bumping table: A suspended table, capable of limited movement, which is subjected to a series of blows or shocks in the plane of its motion.

Chain cutter machine: Machine used to shear or undercut coal. It consists of a low metal bed frame, upon which is mounted a motor that rotates a chain, to which suitable cutting teeth are attached. It can be used only under certain conditions, viz: When the coal is comparatively free from balls of iron pyrites, or when the roof is good and props are not used close to the face of the coal. It can not be used to undercut coal having a squeeze upon it. Machines of the ordinary type perform their work by making a forward cut under the coal, then being withdrawn and moved over to reach fresh coal. This process is repeated across the face of the room. The Sullivan machine is fed under the coal but once, and then makes a continuous cut across the face, being withdrawn only at the farther side of the room.

Channeling machine: A machine for making channels in stone; that is, cutting the stone into blocks without the use of explosives. Its several forms are the track channeler, being a machine mounted on a truck running on a track, carrying a boiler furnishing steam to the machine; or the boiler may be omitted, the machine being driven by compressed air from mains; or the truck may carry a reheater for reheating the compressed air before it reaches the machine; the undercutting track channeler, similar to the above, but without boiler and cutting horizontally; the bar channeler, in which the cutting machine travels on a stationary bar. Any of these machines may be driven by either steam or compressed air.

Chilian mill: An apparatus in which the ore is crushed under vertical rollers running in a circular inclosure with a stone or iron base or die. The rollers rotate on a horizontal axis and also around a common vertical center.

Coal breaker: A machine for crushing lump coal as taken from the mine. It is also adapted for cleansing and sorting.

Coal conveyer: See Conveyer.

Coal cutter: See Pick machine.

Coal washer: A machine in which coal that has been broken and assorted is finally washed to deprive it of the dust and dirt adhering.

Compressor: See Air compressor.

Concentrator: General name applied to all machines for concentrating the mineral values of an ore to a smaller bulk in order to get rid of as much superfluous material as practicable.

Conveyer: An endless belt or chain device for transporting ore or coal.

Crossover dump: A contrivance for dumping cars on the mine tipple, which automatically dumps the car, restores it to its original position, and returns it to the mine.

Crusher: See Breaker.

Diamond drill: See Drill.

Dredge: A machine used in placer mining where streams can not be diverted from their course so as to expose the bed, or where bench placers do not have sufficient water for hydraulicking. A floating dredge is used for mining gravel under water; a traction dredge for "dry" or land mining. Dredges may be divided into two classes—those using a line of buckets on an endless chain, and those of the dipper type, which use a single bucket like a steam shovel.

Drill: A machine operated by steam, electricity, or compressed air, for boring. They are of two classes, percussive and rotary. A percussion drill consists of a cylinder in which works a piston carrying a long piston rod, and which is supported in such a manner that the drill, clamped to the end of the piston rod, alternately strikes and is withdrawn from the rock as the piston reciprocates back and forth in the cylinder. Means are provided by which the piston rod and drill turn slightly on their axis after each stroke. Rotary drills differ from percussive drills in the fact that the drill makes its way into the rock by a boring action produced by the axial rotation of the drill rod. Diamond drills are of the latter class, the drilling tool being a hollow cylinder armed with diamonds on its cutting end. See also Hydraulic boring machine; Gadder, etc.

Drill steel sharpener: A device driven by compressed air for sharpening steels for drills, channelers, etc.

Electric drill: See Drill.

Electric locomotive: See Mine locomotive.

Electric pump: A mine pump operated by electricity.

Elevator: A machine, consisting of series of buckets attached to an endless chain or belt, for lifting materials from one height to another.

Feeder: A machine for automatically delivering ore in proper quantities and at a definite rate to stamp batteries, roll grinders, etc.

Gadder: A machine by which holes are inserted into the side of the bench, for the insertion of plugs and feathers, by means of which the blocks are separated in the quarry. It may be driven by steam or compressed air.

Gravity stamp: See Stamp mill.

Grinder: See Breaker; Ball grinder; Stamp mill, etc.

Haulage engine: A stationary engine for hauling mine cars by means of tail rope or endless rope systems.

Header: A machine used principally for entry dividing, especially where it is not desired to make lump coal, and where the work must be pushed rapidly. The machine cuts a cylinder of coal about 4 feet in diameter and about 5 feet in length.

Hoisting engine: An engine for hoisting men or materials from a mine.

Hydraulic boring machine: A machine in which the rock drilling machine is actuated by the force of water under pressure, conducted by pipes to the breast of the tunnel.

Hydraulic coal miner: An apparatus for breaking down coal by means of an expanding plug worked by hydraulic pressure.

Jaw crusher: See Breaker.

Jig: A machine in which concentration is effected by giving a column of water a pulsating motion, or by giving the grating and screen, upon which a bed of ore lies, a short reciprocating motion, the resistance of the water lifting up the bed on the down stroke of the piston or grating and the particles assorting themselves as they settle back. The principle of the jig is the tendency of the particles of a bed of ore in water, when approximately of the same size, to arrange themselves in layers according to their specific gravity when the bed is kept sufficiently open to allow the particles to move freely among themselves.

Keeve: A round tub in which the separation is effected by means of stirring paddles, attached to and operated by a vertical shaft passing up through the center of the tub, and by hammers automatically striking the outside of the tub.

Long-wall mining machine: A machine especially designed for undercutting a long-wall face. It consists of an engine or motor mounted on a bed frame and a large cutter wheel in the periphery of which are placed the cutters or bits in a manner similar to that employed in setting the cutters in a chain cutter machine. The bed frame is mounted on wheels which run either on a single rail or an ordinary track laid parallel to the face of the coal. In machines of the Sullivan type the cutter consists of a bar of oblong shape, on which runs a chain carrying cutters or bits. This bar is similar to that used in the chain cutter machine. The machine travels along the bottom of the mine on a flat steel shoe, rails being unnecessary for its operation. The machine takes its motion along the face from a feed chain.

Mechanical conveyer: See Conveyer.

Mill: See Stamp mill.

Mine locomotive: Small, compactly built locomotive for use in mines. In the steam mine locomotive the water tank is set over the boiler, and the smokestack and top of the cab are on a level low enough to permit entrance into the mine passages. The compressed air locomotive requires a stationary air compressing plant and usually pipe lines to convey the compressed air to convenient points in the mine for charging purposes. The electric locomotive also requires a power generating station and is operated in a manner similar to an electric trolley car, using a conducting wire along the haulage road. A variation of the electric mine locomotives is the rack rail locomotive. This locomotive is propelled by sprocket wheels that mesh with the stationary rack laid parallel with the rail, the object being to obtain a great drawbar pull from a light locomotive of small outline dimensions. It is also able to climb steep grades. The electric current is carried to the locomotive in the rack and returned in the track rail.

Ore breaker: See Breaker.

Ore conveyer: See Conveyer.

Ore crusher: See Breaker.

Pick machine: A reciprocating percussive machine used to shear or undercut coal, etc. In undercutting the machine is mounted on small wheels; in shearing, these are removed and large wheels substituted.

Pneumatic drill: See Drill.

Pneumatic pump: A pump operated by compressed air.

Pneumatic stamp: See Stamp mill.

Pulsometer: A water raising device on the principle of the Savery engine. It will raise water by suction to a height of about 26 feet and, if necessary, force it to a height of about 100 feet. Its utility in mining operations lies in the fact that it will pump anything that can get past the valves, including mud, gravel, etc.

Pulverizer: See Roll crusher; Ball grinder; Stamp mill, etc.

Pump: See Steam pump; Sinking pump; Pulsometer, etc.

Riddle: A shaking screen with plane surface. They may be divided into four groups—shaking screens having an endwise or sidewise motion in the plane of the screen, or nearly so, with or without a bump; pulsating screens having an up-and-down motion perpendicular, or nearly so, to the plane of the screen; gyrating screens with a circular or elliptical motion in the plane of the

screen; gyrating screens with motion in a vertical plane parallel to their lengths.

Rock breaker: See Breaker.

Roll crusher: A machine for crushing ore to definite sizes. In roll crushers the ore is broken between two cylinders revolving in opposite directions on parallel horizontal axes.

Roller mill: A form of crushing machine in which the crushing is done by rollers moving around in a horizontal pan. They are of two general types, radial and centrifugal. In the radial roller mill the axis of the roller is a continuation of the radial arm. The rollers of the centrifugal mill revolve on independent axes and are free to swing outward in a radial direction, the rapid revolution of the central spindle causing the rollers to press against a hardened ring die in the side of the pan. See, also, Chilian mill.

Screen, revolving: A cylindrical rotating device consisting of perforated plate or woven wire for assorting material into different sizes. See, also, Trommel.

Screen, shaker: A device made of perforated plate, bars, or woven wire, to which is imparted a reciprocating motion for the purpose of separating material into different sizes. See, also, Riddle.

Shaft excavator: A system of apparatus for sinking shafts in coal mines.

Shearer: A machine for making vertical cuts in a stratum of coal. See, also, Pick machine.

Sinking pump: Portable pump used to drain water from the shaft bottom. It is especially adapted to the recovery of flooded mines. These pumps are suspended by a chain attached to eyebolts in the pump, and are provided with clamps for attaching them to the timbers in the shaft when it is desired to fix them in position temporarily. As the shaft gets deeper, the chain may be lengthened and an extra joint placed on the upper end of the delivery pipe. A single steam pipe down the shaft supplies both the sinking pump and the main pump. Electric sinking pumps are operated by electricity generated in a surface power plant.

Stamp mill: A mill for reducing ores to a comminuted state preparatory to extracting the precious metals by amalgamation. Stamps may be divided into three classes: Steam stamps, pneumatic and spring stamps, and gravity stamps. In the first-named class the pestles are raised and forced down by a steam piston. In pneumatic and spring stamps the power for lifting and forcing down the stamp is applied by a crank, while the shock to the machine and the variation of length of stroke are taken up by an air cushion or by a spring. The pestles of a gravity stamp are raised by power and fall by their own weight.

Steam drill: See Drill.

Steam pump: Force pump operated by steam acting upon the piston of a steam engine directly connected to the pump.

Steam stamp: See Stamp mill.

Trommel: A revolving screen, usually cylindrical in shape, in which ore is screened by causing it to slide by the revolution of the screen instead of a shaking movement. Tandem trommels have screens of two or more sizes on the same shaft, forming one continuous cylindrical or conical surface. Concentric trommels have two or more screens placed one outside of the other on the same shafts.

Undercutting machine: Machine for undercutting coal in the mine. See, also, Pick machine; Chain cutter machine, etc.

Vanner: A machine for separating heavy minerals from lighter by gently shaking or vanning, the mild agitation keeping the particles of the lighter mineral in suspension while the particles of the heavier mineral sink to the bottom.

Ventilating fan: A blower or ventilator for supplying air to mines.

XVII.

QUANTITY AND VALUE OF PRODUCTS.

Scope of the statistics.—For census purposes the productive industries of the country are divided into four broad groups—agriculture, manufactures, mining, and fisheries. It has been the endeavor since 1870 to preserve the distinction between these groups, but the trend of industrial development has been toward the consolidation of interests so as to bring under one management the production of both the raw material and the finished product. This tendency is especially noticeable in mining and manufacturing, and has caused these industries to overlap at many points, making a statistical separation impossible. The relationship between the two industries is discussed on page 9. It is evident that the difficulties attending a separation are increasing with the development of the resources of the country. If both industries were enumerated at the same time, it would be possible to so word the schedule as to obtain a consistent report covering the entire operations and at the same time make a practicable separation of the statistics. On the other hand, mines and quarries are a branch of the extractive industries, which include all those industries dealing in the natural products of the earth and are, in theory at least, allied to agriculture, but the statistics of agriculture for the Twelfth Census do not include any data relating to mines or quarries.[1]

The limitations of the statistics for manufactures are not so easily defined. Section 7 of the act of Congress of March 3, 1899, providing for the Twelfth and subsequent censuses, confined the inquiry to "manufacturing and mechanical establishments." If the law had not contained special provision for a mining census, this section would in all probability have been construed to cover mines and quarries, as was done in early censuses. In the absence of a direct provision of law, the limitation of the census of manufactures was not fixed arbitrarily, but was determined by the conditions and requirements of those industries which are on the border line between mining and manufacturing. This has resulted in some duplication in the statistics of production. For instance, an establishment engaged in the manufacture of cement that operated a quarry from which it obtained the raw material was reported as a manufactory, but it was also reported in the mining census as a quarry.

The two industries being thus interdependent, the duplication incident to the combination of their products can be eliminated only by ascertaining the quan-

[1] Twelfth Census, Report on Agriculture, Part I, pages xiii and xiv.

tity and value of the mining products consumed in manufacture. This was attempted at the Twelfth Census by obtaining from manufacturers the cost of materials purchased in a raw state.

Standard of measurement.—In statistics of manufactures the standard of measurement is limited to the dollar because of the great diversity of products and the impossibility of obtaining a uniform unit of quantity. For similar reasons the same unit of measurement is used in presenting the total for all mining products. The quantity is a more exact indication of the relative importance of a given product than is its value, and the quantity is shown for the majority of the minerals; but the impossibility of applying this standard is found when an attempt is made to reduce the different units to a uniform basis and give to each its true weight. For instance, there were 35,567,410 long tons of iron ore, 36,940,710 long tons of anthracite coal, 260,216,844 short tons of bituminous coal, 59,557,715 ounces of gold and silver, 34,291 flasks of quicksilver, and 89,275,302 barrels of petroleum reported as produced in the United States during the year 1902. These various units can not be reduced to a uniform basis, and the aggregate value is necessarily used in presenting the total. The value of the annual production of gold and silver was almost half as great as that of anthracite and bituminous coal, but there were nearly ten times as many wage-earners employed in the production of coal as in the production of the precious metals.

The changes in value per unit have resulted in a decrease in the total value of certain products, although the quantity has increased, while for others the percentage of increase in the total value has exceeded that of the total quantity. By the use of the quantity the uncertainties due to fluctuation in prices are eliminated. Table 58, which shows the production and commercial value of silver for selected years, as computed by the Director of the Mint, illustrates, for two periods, the increase in quantity accompanied by a decrease in value, and for three periods, the increase in quantity accompanied by a smaller increase in value.

TABLE 58.—*Production and commercial value of silver.*

YEAR.	FINE OUNCES.		COMMERCIAL VALUE.	
	Number.	Per cent of increase.	Amount.	Per cent of increase.
1880	30,320,000		$34,720,000	
1885	39,910,000		42,500,000	
Difference	9,590,000	31.6	7,780,000	22.4
1886	39,440,000		39,230,000	
1892	63,500,000		55,563,000	
Difference	24,060,000	61.0	16,333,000	41.6
1890	54,500,000		57,225,000	
1891	58,330,000		57,630,000	
Difference	3,830,000	7.0	405,000	0.7
1894	49,500,000		31,422,000	
1902	55,500,000		29,415,000	
Difference	6,000,000	12.1	[1] 2,007,000	[1] 6.4
1901	55,214,000		33,128,000	
1902	55,500,000		29,415,000	
Difference	286,000	0.5	[1] 3,713,000	[1] 11.2

[1] Decrease.

For three of the periods shown in the above table the percentage of increase in the quantity of silver produced exceeded the increase in commercial value, and for two there was an absolute decrease in value with a small rate of increase in quantity. The greatest difference is shown for the period from 1894 to 1902. The production for 1902 showed an increase of 6,000,000 ounces, or 12.1 per cent over the production of 1894, while the commercial value decreased by $2,007,000, or 6.4 per cent. There was also a decrease of $3,713,000, or 11.2 per cent, in the value reported for 1902 as compared with 1901, although the production increased by 286,000 fine ounces, or five-tenths of 1 per cent.

While in the case of silver the production has increased more rapidly than the value, the reverse is true for coal, the value having increased more rapidly than the production. This is shown by the following table, giving the quantity, value, and percentage of increase in the production of anthracite and bituminous coal:

TABLE 59.—PRODUCTION OF ANTHRACITE AND BITUMINOUS COAL.[1]

YEAR.	QUANTITY.		VALUE.		AVERAGE PRICE PER TON.		AVERAGE NUMBER OF EMPLOYEES.	
	Short tons.	Per cent of increase.	Amount.	Per cent of increase.	Amount.	Per cent of increase.	Number.	Per cent of increase.
1891	117,901,238		$117,188,400		$0.994		205,803	
1892	179,329,071		207,566,381		1.160		341,943	
Difference	61,427,833	52.1	90,377,981	77.1	0.166	16.7	136,140	66.2
1898	219,976,267		208,023,250		0.95		401,221	
1899	253,741,192		256,094,234		1.01		410,635	
Difference	33,764,925	15.3	48,070,984	23.1	0.06	6.3	9,414	2.3
1898	219,976,267		208,023,250		0.95		401,221	
1902	301,590,439		367,032,069		1.22		518,197	
Difference	81,614,172	37.1	159,008,819	76.4	0.27	28.4	116,976	29.2

[1] United States Geological Survey, "Mineral Resources of the United States," 1902.

The per cent of increase in the value of the production of coal for each of the periods covered by the above statement was greatly in excess of the percentage of increase in production and in the number of employees engaged in the industry. The production for 1902, as compared with 1898, increased by 81,614,172 short tons, or 37.1 per cent, while the value increased $159,008,819, or 76.4 per cent, the average value per ton increasing 27 cents, or 28.4 per cent, and the number of employees 116,976, or 29.2 per cent.

The increase in value does not convey a correct idea of the importance of the industry from the standpoint of employment, but there is a close affinity between the quantity of the product and the number of wage-earners. The production of a mine depends upon the thickness of the vein; the purity of the ore; the ease of working, as influenced, for example, by the necessity for drainage; the ability and energy of the superintendent and bosses; and the state of the labor market and the character of the laborers. All of these factors influence the cost of production, which also depends upon the price of supplies, the freight charges of transportation companies, and the character of the financial management.

Value of products for 1902.—The value of product reported at the census of 1902 was the value f. o. b. at the mine or quarry of all mineral or stone mined during the year. A similar value was given for the production of petroleum, but for natural gas the value reported was the price to the consumer as obtained from the books of the companies. The total value of products for all mines, quarries, and wells amounted to $796,826,417. As explained on pages 9 and 10, in some instances this value includes products that have been subjected to manufacturing processes carried on at the mine or quarry. It is the amount received by the operators of the mines or quarries and should not be confused with the value of the metallic contents of ores, such as refined gold and silver or fine lead, which are sometimes classed as a part of the value of the mineral products of the country. The total value of the commercial mineral production reported by the United States Geological Survey amounted to $1,260,637,415 for the year 1902. The difference between this value and the census value is explained on pages 129 to 131.

The value of the products reported at the census of 1902 is shown for each of the different classes of minerals, and these classes are also grouped in order to bring together the products of a similar character or of which similar uses are made. In all cases where the quantity of the product could be reported it is presented in connection with its value, and the statistics are discussed in detail in the separate reports for each mineral. The salaries, wages, and expenses reported for each mineral cover the development work carried on during the year at productive mines, and their sum for some mines necessarily exceeds the value of the products. In the natural gas industry the expenses incident to distribution are charged to the state in which they were incurred, while the value is reported for the state from which the product was obtained. For these and other reasons the expenses should not be considered as indicating the cost of the product, nor the difference between the total expenses and the value of the product as the profit of mining operations.

The statistics of production are discussed in detail in the separate reports for the different minerals and also in the presentation by states.

The following statement shows the value of the products for all minerals grouped according to their character or uses and the percentage that each group is of the total:

Value of products for groups of minerals and percentage each is of the total: 1902.

GROUP.	PRODUCTS.	
	Value.	Per cent of total.
Total	$796,826,417	100.0
Metallic	215,453,587	27.0
Fuel	469,297,671	58.9
Structural materials	96,370,559	12.1
Abrasive materials	1,177,711	0.2
Chemical materials	10,618,669	1.3
Pigments	564,039	0.1
Miscellaneous	3,344,181	0.4

Of the $796,826,417 reported as the value of products of mines, quarries, and wells, $469,297,671, or 58.9 per cent, is included in the group of "fuels," composed of coal, petroleum, and natural gas. The production for the "metallic" group, which includes copper ore, gold and silver, iron ore, lead and zinc ore, manganese ore, and quicksilver, was valued at $215,453,587, or 27 per cent. The structural materials, comprising stone, cement, clay, and slate, were valued at $96,370,559, or 12.1 per cent. All other substances obtained from mines and quarries were valued at $15,704,600, or 2 per cent of the total. It appears, therefore, that the mineral products of the country are composed very largely of fuels and metallic ores, these two groups forming 85.9 per cent of the total.

The proportions of the total value of the products obtained from the mines and quarries in different geographic divisions of the United States are shown by the following statement:

Value of products by geographic divisions: 1902.

DIVISION.	Value of products.	Per cent of total.
United States	[1] $796,826,417	100.0
North Atlantic	274,436,816	34.4
South Atlantic	71,571,074	9.0
North Central	251,874,635	31.6
South Central	50,044,483	6.3
Western	[1] 148,899,409	18.7

[1] Includes value of Alaskan coal and Hawaiian stone products.

The North Atlantic and the North Central states cover the principal mineral producing sections of the country. The value of the products of the two divisions amounted to $526,311,451, or 66 per cent of the total for the United States. Of the $274,436,816 reported as the value of products for the North Atlantic states, $236,871,417, or 86.3 per cent, was obtained from the mines, quarries, and wells of the state of Pennsylvania. The products of this state were composed very largely of coal, petroleum, and natural gas. Fuels were also the predominating minerals in the North Central division, their production amounting to $132,031,098, or 52.4 per cent of the total.

The value of the production of the Western states was only 18.7 per cent of the total for the United States. The chief products were gold and silver, copper ore, and lead and zinc ore, the production of these minerals amounting to $107,841,021 in value, or 72.4 per cent of the total for this division.

The value of the production of the South Atlantic and South Central states amounted to $121,615,557, or 15.3 per cent of the total for the United States.

Value per unit of measure.—The great variety of minerals included in the census reports and the wide variation in the value of products restricts the use of figures in ascertaining the average value per ton or other unit of production, there being comparatively few minerals for which the census statistics can be used for this purpose. This is illustrated by the following comparative table, presenting the quantity, value, and average value per unit of measure for selected minerals:

TABLE 60.—COMPARATIVE SUMMARY OF QUANTITY, VALUE, AND AVERAGE VALUE PER UNIT OF MEASURE OF PRODUCTS FOR SELECTED MINERALS: 1902 AND 1889.

MINERAL.	1902			1889		
	Quantity (short tons).	Value.	Average value per unit of measure.	Quantity (short tons).	Value.	Average value per unit of measure.
Asbestos	2,505	$46,200	$18.44	30	$1,800	$60.00
Asphaltum and bituminous rock	66,238	236,728	3.57	51,735	171,537	3.32
Barytes	61,668	203,154	3.29	21,460	106,313	4.95
Borax	19,142	2,383,614	124.52	[1] 4,000	[1] 500,000	125.00

[1] Not included as part of the census; no statistics other than production reported.
[2] Stones.
[3] Not reported.
[4] Barrels.
[5] Long tons.
[6] Copper contents of all ores mined.
[7] Pounds.
[8] Fine gold contents of auriferous ores and placer bullion.
[9] Troy ounces.
[10] Includes land plaster, calcined plaster, and crude gypsum.
[11] Nonargentiferous lead ore and lead contents of argentiferous and copper ores.
[12] Values not separable in 1889.
[13] Includes slate ground as a pigment, 2,000 long tons, value $20,000.
[14] Flasks.
[15] Zinc ore and zinc contents of auriferous and argentiferous ores.

While, with a few notable exceptions, the average values per unit for the minerals included in the above table indicate a general increase in 1902 as compared with 1889, the averages should not be accepted as reflecting the actual conditions. As explained on pages 8 and 9, the products were not reported at the two censuses on a uniform basis. The theory of both censuses was evidently to report, as a rule, the crude products, but in a number of cases refined or partially refined products were necessarily included. It is impossible to determine the exact extent to which the partially manufactured product has been included in the totals for either census. The quantities and value of coal, iron ore, petroleum, and other minerals for which a crude product is necessarily reported, or of buhrstones, millstones, oilstones, cement, and other substances reported in a manufactured or partially manufactured state may be accepted as a basis for computing the average value, although these values are in every instance the value f. o. b. at the mine and include different grades of a general class or group. For instance, different varieties of cement and different grades of the same variety are included in the totals for both censuses; therefore an average price obtained from such a combination has little significance. Where practicable the average value per unit is given in the reports on the separate minerals.

By-products.—In adopting the classification of minerals used by the United States Geological Survey it was necessary to assign to certain classes products obtained from mines or quarries reported under other classifications. The class of products included in the totals for each mineral are described in the separate reports and also in the discussion of "classification," pages 24 to 35. This method of assigning the products found the widest application in the group of "abrasive materials." Of the total value—$1,177,711, reported for this group of minerals—$444,539, or 37.7 per cent, represents products obtained from quarries included in other classifications and under which the statistics for employees and wages and expenses are shown.

In four of the classes of materials included under abrasives a portion of the products was obtained from quarries included under other classes of minerals. Of the $667,431 reported as the value of grindstones and pulpstones, $403,066, or 60.4 per cent, was obtained from quarries included under the classification of "sandstones and quartzites." This value, $403,066, should therefore be added to the classification of sandstones and quartzites in order to obtain a value consistent with the salaries, wages, and other expenses.

The following statement shows the quantity and value of each class of products included under abrasive materials and also the quantity and value of each class obtained from other classifications:

Abrasive materials and the quantity and value of such materials obtained from quarries included under other classifications: 1902.

ABRASIVE MATERIALS.	TOTAL ABRASIVE MATERIALS.		OBTAINED FROM QUARRIES CLASSIFIED AS—							
			Sandstones and quartzites.		Siliceous crystalline rocks.		Talc and soapstone.		Grindstones and pulpstones.	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.	Quantity (stones).	Value.	Quantity (short tons).	Value.	Quantity (short tons).	Value.
Total		$1,177,711	35,683	$411,938	100	$1,425	175	$1,436	595	$29,740

[1] Stones.

XVIII.

MINING OPERATIONS OF GOVERNMENTAL INSTITUTIONS.

In addition to the statistics for mines and quarries operated by private enterprise, the mining census includes the statistics for 3 quarries operated by the United States Government, 41 quarries and 79 natural-gas wells operated by city or town governments; also 2 coal mines, 1 iron mine, 35 natural-gas wells, and 18 quarries operated by penal or eleemosynary institutions. In order to preserve the distinction between the mining operations controlled by governmental institutions and those conducted by private enterprise the statistics for the former work are presented separately, and Table 61 summarizes the totals for the mines, quarries, and wells controlled by each of the four classes of governmental institutions.

TABLE 61.—SUMMARY, MINING OPERATIONS OF GOVERNMENTAL INSTITUTIONS: 1902.

CHARACTER.	Number of mines, quarries, and wells.	Number of operators.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS.		CONTRACT WORK.		Miscellaneous expenses.	Cost of supplies and materials.	Value of product.
			Number.	Salaries.	Average number.	Wages.	Amount paid.	Number of employees.			
Total	179	78	106	$67,661	484	$270,938	$29,184	38	$46,330	$200,909	$1,071,153
United States	3	3	9	6,155	73	39,699	.....	.....	1,060	16,530	80,353
Municipal	120	48	51	28,921	305	167,886	22,436	30	40,123	122,136	494,037
Penal	19	19	46	32,585	105	63,028	3,248	.....	4,547	61,323	470,069
Eleemosynary	37	8	.....	.....	1	325	3,500	8	600	920	26,694

The wage-earners shown in Table 61 do not include the convicts in penitentiaries or the value of the work of such convicts when employed on contract, lease, or otherwise, nor do they include the number of inmates of eleemosynary institutions thus employed. The salaried officials reported were not engaged exclusively in the supervision of the mines and quarries. It is probable that most of them had other duties to perform in and about the institutions, and miscellaneous duties are also required to some extent of the wage-earners. The number of employees reported, therefore, should not be accepted as the number engaged exclusively in mining operations.

Federal and municipal quarries and wells.—Of the 179 quarries and wells operated by governmental institutions, 123 were controlled by the United States and by city or town governments, and the statistics for such mining operations are presented in Table 62.

TABLE 62.—MINES, QUARRIES, AND NATURAL-GAS WELLS OPERATED BY THE UNITED STATES AND CITY OR TOWN GOVERNMENTS: 1902.

	Number of mines, quarries, and wells.	Number of operators.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS.		CONTRACT WORK.		Miscellaneous expenses.	Cost of supplies and materials.	Value of product.

Pennsylvania	1	1	.....	.....	2	677	.....	.....	.....	190	1,100

The mining operations carried on by the United States and by municipal governments gave employment to 378 wage-earners, to whom $207,585 was paid in wages during the year. Of this number 366, receiving $200,181 in wages, were engaged in operating quarries, from which were obtained products used in the construction of public buildings and highways, dams, canals, etc. The products of these quarries were valued at $369,128. Of the 28 quarries operated by municipalities and engaged in quarrying siliceous crystalline

rocks and sandstones and quartzites, 21 were located in Massachusetts, and their products were valued at $172,454, or 70.3 per cent of the total for all quarries of these classes. The municipal quarries in Massachusetts were engaged exclusively in the preparation of road material. There were 79 natural-gas wells operated by 11 municipalities, the gas, valued at $205,262, being used in the operation of electric light and power plants. The gas was also used for the illumination of public buildings, streets, and grounds, and in some instances, was sold to private consumers.

Penal institutions.—The United States Bureau of Labor has made two reports on convict labor.[1] From the latter of these reports, which was published in July, 1896, it appears that the practice of employing convicts in mines and quarries and in the dressing and preparation of stone for building purposes, or for the construction of highways, prevailed in a number of state penitentiaries. The value of such work for the year 1895 was reported at $1,578,905. Work of this character was also done to a considerable extent by the inmates of penal institutions, where the regulations are less rigorous than in state penitentiaries. The majority of the convicts thus employed were not engaged directly by the state, but were worked under a contract, lease, or other system, and therefore the value of their work reported to the Bureau of the Census would be included in the returns of mines and quarries operated by private enterprise and reported under the head of "contract work." The statistics for the 19 mines and quarries operated by penal institutions are presented in the following table:

[1] Report of the United States Commissioner of Labor, 1886, and Bulletin of United States Department of Labor, July, 1896.

TABLE 63.—MINES AND QUARRIES OPERATED BY PENAL INSTITUTIONS: 1902.

	Number of mines, quarries, and wells.	Number of operators.	Salaried officials, clerks, etc.		Wage-earners.		Contract work, amount paid.	Miscellaneous expenses.	Cost of supplies and materials.	Value of product.

South Dakota	1	1	1	560	2	1,240	.....	.....	2,700	10,000
Siliceous crystalline rocks	2	2	4	3,544	13	8,000	.....	.....	1,024	18,716
Minnesota	1	1	3	2,644	13	8,000	.....	.....	705	13,464
Pennsylvania	1	1	1	900	.....	.....	.....	.....	319	5,252

The 105 wage-earners shown in Table 63 as engaged in the mines and quarries operated by penal institutions do not include the convicts thus employed. They represent only the number of guards or free labor necessarily employed in the supervision of the work or in the performance of duties that can not be intrusted to the inmates. The production of the quarries thus operated was utilized in the erection of new buildings, retaining walls or sidewalks, or was broken into riprap and macadam by the prisoners and used in the construction of highways. The 2 coal mines operated by penal institutions gave employment to more than half of the salaried officials and wage-earners engaged in operating the mines and quarries controlled by such institutions. The coal mined was valued at $390,054, or 83 per cent of the total value of the production of all mines and quarries of this class.

Eleemosynary institutions.—The statistics for the 2 stone quarries and 35 natural gas wells operated by eleemosynary institutions are presented in Table 64.

TABLE 64.—QUARRIES AND NATURAL-GAS WELLS OPERATED BY ELEEMOSYNARY INSTITUTIONS: 1902.

XIX.

THE VERIFICATION OF THE MINING CENSUS.

Statistics of the mineral products of the country are collected by the Bureau of the Census, also by the United States Geological Survey and by the mine inspectors and geologists of different states. When the statistics compiled by these various offices relate to the same mineral and cover the same year as that covered by the Census reports there should be a certain degree of harmony in the results, but this is disturbed because various methods are followed in collecting and compiling the data, according to the object of the report. The statistics in some of the reports represent a year's production; in others they represent the product placed on the market during the year; in some they give the quantity and value of the crude material; and in others they show the quantity and value of the product partly manufactured or prepared for the market.

Comparison with Geological Survey.—The reports of the United States Geological Survey are published yearly and are harmonized with the reports for the preceding year, also with prior Census reports. An agreement between the statistics of the Survey and those of the Bureau of the Census was one of the objects of the cooperative work of the two offices in collecting the reports for the mining census of 1902. The quantity and value of the different minerals as compiled by the two offices are compared in the following table:

TABLE 65.—COMPARISON OF MINERALS AND MINERAL PRODUCTS REPORTED BY THE BUREAU OF THE CENSUS AND THE GEOLOGICAL SURVEY: 1902.

MINERAL OR MINERAL PRODUCT.	BUREAU OF THE CENSUS.		GEOLOGICAL SURVEY.	
	Short tons.	Value.	Short tons.	Value.
Antimony	(1)	(1)	3,561	$634,506
Asbestos	2,505	$46,200	[2] 1,005	[3] 16,200

Zinc ore	[31] 527,121	9,006,361	[15] 156,927	14,625,596
All other minerals	[32] 3,536	[32] 49,256	[33] 3,823	[33] 35,344

[1] Not reported by the Bureau of the Census.
[2] Quantity marketed in 1902.
[3] Value of product marketed in 1902.
[4] Includes residual asphaltum product from petroleum refineries not reported by the Bureau of the Census.
[5] Long tons.
[6] Includes 862 short tons of boric acid, valued at $155,000, not reported by the Bureau of the Census.
[7] Stones.
[8] Not reported.
[9] Barrels.
[10] Includes all manufactured cement. Bureau of the Census reports only cement manufactured at quarries.
[11] Pounds, copper contents of all ores mined.
[12] Quantity of refined metal, value at New York city.
[13] Survey reports value of product finished and marketed. Bureau of the Census reports value at quarry.
[14] Troy ounces. Fine gold contents of auriferous ores, and placer bullion, exclusive of 403,730 ounces, valued at $8,345,800, estimated by the Director of the Mint as produced in Alaska.
[15] Quantity of refined metal.
[16] Pounds.
[17] Estimated as crude.
[18] Does not include 13,275 tons of manganiferous iron ore used in production of spiegeleisen.
[19] Nonargentiferous lead ore and lead contents of argentiferous and copper ores.
[20] Survey reports an added value of $107,794 for a product which was finished away from quarries.
[21] Not reported; entire production obtained in the refining of auriferous ores.
[22] Troy ounces. Quantity of refined metal. Value at San Francisco.
[23] Cinnabar mined, but not reduced.
[24] Not reported by the Geological Survey.
[25] Flasks. Quantity of refined metal. Value at San Francisco.
[26] Bureau of the Census statistics include only the sand produced in sandstone quarries by crushing the rock. The Geological Survey includes sand produced in sandstone quarries as well as glass sand obtained from banks.
[27] Troy ounces. Fine silver contents of argentiferous ores, and placer bullion, exclusive of 92,000 ounces, valued at $118,950, mined in Alaska.
[28] Includes value as follows: Limestones and dolomites (less value of iron flux), $25,170,549; marble, $5,044,182; sandstones and quartzites, $10,601,171; siliceous crystalline rocks, $18,257,944; slate, $5,696,051.
[29] Does not include limestone quarried for cement valued at $210,798.
[30] Includes 391 tons of soapstone, valued at $2,340, classified by the Bureau of the Census under mineral pigments, crude.
[31] Zinc ore and zinc contents of auriferous and argentiferous ores.
[32] Includes chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile.
[33] Includes chrome ore, magnesite, nickel (refined metal), cobalt oxide, and rutile. Does not include molybdenum.

As explained on page 24, in the reports for the Bureau of the Census, the different mines and quarries were classified according to their product of chief value. By this practice there was assigned to some classifications a production of ores which included several metals, and in order to compare the Census data with the reports of the Geological Survey, the total production of gold, silver, copper ore, and lead and zinc ore is given in the foregoing table, irrespective of the class of ore with which they were mined or from which they were obtained. The products, therefore, do not agree with the products shown elsewhere for the same class of minerals. For instance, the copper contents of all ores, as shown by Table 65, amounted to 639,033,392 pounds, valued at $71,192,014, but the products of the copper mines, classed as such by the Bureau of the Census, amounted to 11,780,064 short tons of ore, valued at $51,178,036. Notwithstanding the above arrangement the production of gold as reported by the Geological Survey exceeds that of the Census report by 627,961 ounces, valued at $12,981,110; and of silver by 1,301,656 ounces, valued at $1,682,950, both exclusive of Alaska; of copper by 20,475,252 pounds, valued at $5,376,940. This excess in the reports of the Geological Survey is due to the fact that the totals for the Bureau of the Census are based on the reports of the mine operators representing the production of the mines, while those for the Geological Survey are based on the reports of smelters and refineries, and show the amount of refined metal marketed during the year rather than the amount produced by the mines. The value of 1 ton of ore assaying 1 ounce of gold per ton may have been computed, in the settlement between the miner and the smelter, at the rate of $19 per ounce of fine gold contents, from which further deductions were made for treatment and freight, leaving to the miner perhaps not more than $10 net, whereas the value of 1 ounce of refined gold bullion would be reported by the United States Geological Survey as $20.67. The results of both offices are correct, one aiming to obtain the market value of the refined metal and the other the amount received by the miner for his operations during the year.

The production of lead and of zinc, as reported by the Bureau of the Census, exceeds that of the Geological Survey by 68,125 and 370,194 short tons, respectively, while the value of these metals as reported by the Geological Survey exceeds the value shown in the Census report by $3,958,987 and $5,619,235, respectively. This discrepancy is due also to the fact that the Geological Survey reports the quantity and value of the refined product, the crude product reported by the Bureau of the Census being of greater weight but less value.

That part of the difference which is due to the inclusion of manufactured products by the Survey, under the same or similar mining classifications as those of the Bureau of the Census, is illustrated by asphaltum and bituminous rock. The Bureau of the Census reports 39,220 short tons less than the Geological Survey; these are valued at $528,320, and are the residual asphaltum product of petroleum refineries, which the Bureau of the Census classifies as the result of manufacturing processes. The Bureau of the Census report for mineral pigments, crude, is another illustration. The Geological Survey reports instead mineral paints, which are a manufacture, and its statistics are for the manufactured product marketed, the excess over the Bureau of the Census report being 37,570 short tons, valued at $583,447.

Graphite affords an illustration of the difference due to reporting the production marketed instead of the production mined. The Bureau of the Census values, which are for the production mined, exceed those of the Geological Survey, which are for the production marketed, by $45,400.

All of the differences between the amounts and values reported by the two offices are explained in the footnotes to Table 65, but another illustration may be given. The Bureau of the Census shows no production of antimony, but the Geological Survey reports 3,561 short tons of this metal, valued at $634,506. There was no production of antimony from domestic antimonial ores during the year 1902, and the entire quantity reported by the Geological Survey was obtained from smelting foreign or domestic hard lead ores from regulus or metal or from antimonial ores imported. The production, therefore, has no direct connection with the operations at the mine and was omitted from the mining census.

In addition to the minerals enumerated in Table 65, the annual reports of the Geological Survey show the quantity and value of the following substances which are, for Census purposes, classed as manufactured products, and therefore omitted from the statistics of mining: Aluminum, bromine, coke, pig iron, salt, zinc white, and arsenious oxide. The Geological Survey also reports the production of brick clay, glass sand, and mineral waters. Brick clay is omitted from the mining census, as the manufacture of brick, with that of all other clay products, was reported in the census of manufactures. The value of the material was a constituent of the value of product, and this material was generally mined by the manufacturer. Glass sand is omitted because most of it is obtained from sand banks or from river beds, and such production was not considered as forming a part of the mining or quarrying operations of the country. Glass sand, when obtained from the crushing of sandstone incident to the quarrying of such stone, has been included in the Census report on stone under the classification of "silica sand." Mineral waters are omitted because it is impossible to make a complete enumeration of such waters, and there is very little, if any, labor incident to their

production, the operations consisting entirely in bottling and otherwise making the product ready for the market.

In order to cover the total production of minerals of all classes, the Geological Survey also includes an "estimated value of mineral products unspecified." Beginning with 1889 the value of these miscellaneous minerals has been placed annually at $1,000,000. An estimate of this character was not attempted for the census of 1902, the production being confined to the quantities and values reported by the mine operators. With the exceptions indicated, all of which are due to the difference in the objects of the reports of the two offices, there is an exact agreement in the production of the different minerals as compiled by the Geological Survey and the Bureau of the Census.

Comparison with state reports.—While the state mine inspectors and geologists in a number of the states collected miscellaneous information concerning different minerals, the only uniform compilation of the production relates to anthracite and bituminous coal. The quantities of coal as reported by the Bureau of the Census and by the state officials in several of the principal producing states are shown in the following table:

TABLE 66.—*Yearly production of coal as reported by United States Census and state offices.*

STATE OR TERRITORY.	Bureau of the Census (short tons).	STATE REPORTS.	
		Short tons.	Year ending—
Colorado	7,401,343	7,522,923	Dec. 31, 1902
Illinois	32,939,373	30,021,300	June 30, 1902
Indian Territory	2,820,666	3,243,692	June 30, 1903
Iowa	5,904,766	6,185,734	June 30, 1903
Kansas	5,266,065	5,230,433	Dec. 31, 1902
Kentucky	6,766,984	6,429,419	Dec. 31, 1902
Michigan	964,718	869,228	Dec. 31, 1902
Missouri	3,890,154	4,063,572	Dec. 31, 1902
New Mexico	1,048,763	1,359,530	June 30, 1903
Ohio	23,519,894	23,929,267	Nov. 15, 1902
Pennsylvania:			
Bituminous	98,574,367	98,946,203	Dec. 31, 1902
Anthracite	[1] 36,940,710	[1] 36,911,554	Dec. 31, 1902
Washington	2,681,214	2,690,789	Dec. 31, 1902
West Virginia	24,570,826	23,359,083	June 30, 1902

[1] Long tons.

The production of coal, as reported by the Bureau of the Census, agrees exactly with the production as reported by the Geological Survey; and from the above table it appears that when the reports of the Bureau of the Census and the state officials cover the same year there is a substantial agreement in the quantities reported, the greatest variation being shown for Pennsylvania, where the production of bituminous coal as reported by the state exceeds that shown by the Bureau of the Census by 371,836 tons. A number of the state reports, however, cover the fiscal year ending June 30, while in one instance, Ohio, the report covers the year ending November 15, and no satisfactory comparison can be made with the Bureau of the Census returns.

In addition to statistics of the production of coal the state of Missouri collects information concerning the production of lead and zinc. The production of these metals, as reported by the state office for the year 1902, amounted to 126,831 and 234,903 tons, respectively, as compared with 124,537 and 240,057 tons, respectively, reported by the Bureau of the Census. This is a striking agreement in the quantities compiled by two entirely independent offices. The state of Idaho also collects information concerning the production of lead. The production for 1902, as reported by the state office, amounted to 119,223,000 pounds, as compared with 208,093,202 pounds reported by the Bureau of the Census, the census report exceeding that of the state by 88,870,202 pounds. The production of lead in Idaho is obtained entirely from silver-bearing lead ores, and the total quantity can not be definitely ascertained until the ores have been subjected to smelting processes. The quantities, therefore, were estimated. This fact, in connection with the fact that the reports for the state do not necessarily apply to the quantities obtained from the ores mined during the census year, probably accounts for the marked difference. The quantity of iron ore produced in the state of New Jersey during 1902, as reported by the geological survey of the state, amounted to 443,728 tons, as compared with 441,879 tons reported by the Bureau of the Census.

XX.

MINING AND MANUFACTURING.

The combination of mining and manufacturing by the use of the same capital, wages, expenses, etc., has been accentuated by the consolidation of industrial enterprises, and it is impossible, in many instances, to segregate the statistics so as to show the true totals for each branch of industry. If the statistics for mining and manufacturing were to be taken together it would be easy to find a common term for this union, and comparatively simple to show the aggregate figures; but such a combination would not be a compliance with the act of Congress of March 6, 1902, which provides for mines, mining, quarries, and minerals as a distinct class of census work. Theoretically a perfect mining census should terminate with the delivery of the ore or crude rock at the mine or quarry, but in many cases the employees work indiscriminately in both branches of industry and no value is placed on the ore as it leaves the mine. Where the milling, separating, washing, burning, calcining, or other forms of reduction or manufacture were performed at the mine or quarry, the census of mines for 1902 includes, as a rule, the employees and the expenses involved in the entire work of the establishment. But the absence of uniformity in this respect at prior censuses makes it impossible to prepare satisfactory comparative statistics for a number of the important minerals.

The Twelfth Census of manufactures includes in a number of instances the mining and quarrying oper-

ations which are incident to such manufacturing as the smelting and refining of ores, the manufacture of monuments, tombstones, etc. The statistics for the two branches of industry are therefore to some extent duplicated. The totals, however, are presented in the following table:

TABLE 67.—*Mining and manufactures: 1902 and 1900.*

	Total.	Mining, 1902.	Manufactures, 1900.
Number of establishments	664,250	[1]151,516	512,734
Salaried officials, clerks, etc.:			
Number	435,876	38,128	397,748
Salaries	$443,873,390	$39,020,552	$404,852,838
Wage-earners:			
Average number	5,903,117	581,728	5,321,389
Wages	$2,700,537,970	$369,959,960	$2,330,578,010
Miscellaneous expenses	$1,100,680,624	$71,771,713	$1,028,908,911
Cost of supplies and materials	$7,484,808,385	$123,814,967	$7,360,993,418
Value of product	$13,836,105,983	$796,826,417	$13,039,279,566

[1] Number of mines, quarries, and wells.

The cessation of work in the anthracite coal industry for a number of months during 1902 tends to reduce the value of the statistics for the mining census as representing conditions during a normal year, but with this exception the totals may be accepted as showing the aggregate importance of the two industries during a period of twelve months and the proportion which each contributes to this aggregate. The table indicates that the kindred industries of mining and manufacturing, which include the mechanical industries, gave employment, on an average during the year to 6,338,993 persons, and paid $3,144,411,360 in salaries and wages. Of this total the salaried officials numbered 435,876, or 6.9 per cent, and the wage-earners 5,903,117, or 93.1 per cent. The mining industries contributed 9.8 per cent of the number and 13 per cent of the wages and salaries, respectively, and the manufacturing and mechanical industries 90.2 and 87 per cent, respectively. Of the $13,836,105,983 reported as the gross value of products, mining contributed 5.8 per cent and manufactures 94.2 per cent.

In a few of the basic industries it is possible to follow the production of the mine to the initiatory stage of its manufacture and to ascertain the quantity and value of the product after it has passed through the first manufacturing process; but the comparison of this quantity and value with the quantity and value of the mineral is apt to be misleading. The mineral materials consumed in manufactures are necessarily the result of mining processes carried on at a previous date, and often the manufactured product is composed of different minerals and other substances, some of which are the result of manufactures. For instance, the production of iron ore for 1902 was 35,567,410 long tons and of pig iron 17,821,307 long tons, indicating that each ton of pig iron required about two tons of iron ore, but it is probable that a large proportion of the pig iron was manufactured from iron ore mined during the preceding year and that a considerable proportion of the production mined during 1902 was not used in manufactures until after the expiration of that year. The production of pig iron consumed not only all of the iron ore, but a large proportion of the 39,604,007 short tons of coal from which 25,401,730 short tons of coke were produced, practically all being employed in blast furnaces. The industry also consumed the 11,878,675 long tons of limestone used for fluxing purposes, and large quantities of coal as fuel.

The raw materials reported at the Twelfth Census as consumed in manufactures amounted to $2,389,140,942. Of this total, $1,940,727,048, or 81.2 per cent, were obtained from the farm; $118,803,115, or 5 per cent, from the forest; $319,975,108, or 13.4 per cent, from the mine; and $9,635,671, or four-tenths of 1 per cent, from the sea.[1] These amounts represent the materials consumed during the year ending May 31, 1900, while the products for the mines and quarries, which products were valued at $796,826,417, were for the calendar year ending December 31, 1902. The two amounts, therefore, are not comparable. This lack of comparability is due not only to the fact that the two reports cover different periods, but also to the fact that the value of the products of the mines and quarries includes in many instances the value of finished products ready for consumption. For instance, the amount for the product of mines and quarries includes cement to the value of $24,268,338; finished slate products to the value of $5,696,051; buhrstones and millstones and other finished abrasives to the value of $841,207. It also includes considerable proportions of the products of marble, sandstones and quartzites, siliceous crystalline rocks, anthracite coal, natural gas, and other minerals which were either sold at the quarry as finished products or consumed in other establishments than those engaged in manufactures. But the cost of the materials obtained from the mine and consumed in manufactures does not include the cost of coal, natural gas, or petroleum used as fuel in manufactures. According to the Twelfth Census, all kinds of fuel consumed in manufacturing establishments cost $205,320,632, and there was also paid $10,986,353 for the rent of power and heat. A large proportion of this cost represents the products of mines.

While all manufactures depend upon the production of mines either for raw materials or machinery, the production of metals is the most striking illustration of this interdependence. Of the various metals, iron is the most important, and it is possible to show its production in connection with the production of the minerals upon which it depends. A presentation of this

[1] Twelfth Census, Report on Manufactures, Part I, page cxxxv.

character is made in the following statement, which presents the total production for the United States:

	1902 (long tons).	1889 (long tons).	Per cent of increase.
Iron ore	35,567,410	14,518,041	145.0
Coke[1]	[2]25,401,730	[2]10,258,022	147.6
Limestone flux[1]	12,139,248	6,318,000	92.1
Pig iron[1]	17,821,307	7,603,642	134.4

[1] United States Geological Survey, "Mineral Resources of the United States," 1902.
[2] Short tons.

The ratio of increase in the production of iron ore and pig iron during the period covered by the above statement was 145 per cent and 134.4 per cent, respectively. The production of coke increased 147.6 per cent, and of limestone used as fluxing material 92.1 per cent. The production of iron and steel was valued at $430,954,348 at the census of 1890, and at $803,968,273 at the census of 1900, an increase of $373,013,925, or 86.6 per cent. These industries are dependent upon the production of iron ore, and an increase in its production would necessarily be followed by a corresponding increase in their manufactures.

When the ore and fuel both exist in the same locality the corresponding manufactures naturally develop locally; this is well illustrated by the growth of iron manufactures in Alabama during the last two decades. Whereas at the census of 1880 Alabama ranked fifth in coke and eighteenth in iron and steel, in 1900 the state was second in coke production and sixth in iron and steel manufactures. The rapid growth of manufacturing industries is due to the utilization of the state's rich mineral resources, which were neglected in the earlier years of the century. The state possesses within its borders all the requisites for iron manufacture—iron ore, coking coal, and limestone for flux. The same is true of Colorado, which has developed greatly in coal and iron and the attendant manufacturing industries during the last decade. The following table shows the interdependent growth of the coal and iron and the allied manufactures in these states:

TABLE 68.—INTERDEPENDENT GROWTH IN THE MINING AND MANUFACTURES OF COAL AND IRON IN ALABAMA AND COLORADO: 1902 AND 1889.

	ALABAMA.			COLORADO.		
	1902	1889	Per cent of increase.	1902	1889	Per cent of increase.
Mine products:						
Iron ore, long tons	3,574,474	1,570,319	127.6	306,572	109,136	180.9
Coal, bituminous, short tons	10,354,570	3,572,983	189.8	7,401,343	2,544,144	190.9
Coke, short tons[1]	2,552,246	1,030,510	147.7	[2]1,003,393	187,638	434.7
Limestone flux for furnaces, long tons	[1]1,001,884	221,215	352.9	[1]402,735	46,296	769.9
Manufactures:						
Coke, value[1]	$8,300,838	$2,372,417	249.9	[2]$2,754,341	$643,479	328.0

[2] Includes Utah.
[3] Not reported separately.
[4] For census year 1890.
[5] For census year 1900.

While a considerable portion of the bituminous coal was consumed in the manufacture of coke, large quantities were used as fuel in manufactures generally, and also in other industries; therefore, the increase in its production is not necessarily accompanied by a corresponding increase in the production of iron. It is also probable that a portion of the coal, coke, and limestone produced in these states was shipped out of the state for consumption in manufactures in other sections of the country. During the period of thirteen years covered by this table the quantity of iron ore, coal, coke, and fluxing material more than doubled in both states, and the value of iron and steel and foundry products indicates that there has been a very large increase in the metal industries, though the statistics for them cover a period of only ten years.

Economies of production in manufactures demand the proximity of raw material, and also of a market for the finished product, or convenient transportation facilities for either or both. In the endeavor to secure the benefits incident to the greatest number of these conditions, factories have been located in different sections of the country, according to the relative advantages to be obtained from proximity to materials, market, or transportation facilities. This localization of industries has been in some instances a gradual growth, as in the case of the manufactures in the New England states, and in others a rapid development, following the discovery of exceptional natural advantages, such as the coal and iron fields of western Pennsylvania and of Alabama. Considering the census of manufactures of 1900 and the mining census of 1902 as comparable, Table 69 shows the total value and the proportion of the products of the mines and manufactures in the different geographic divisions of the country.

TABLE 69.—VALUE OF MINE AND QUARRY PRODUCTS AND MANUFACTURES THEREOF, BY GEOGRAPHIC DIVISIONS.[1]

DIVISION.	MINE AND QUARRY PRODUCTS: 1902.						MANUFACTURES BASED ON MINE AND QUARRY PRODUCTS: 1900.			
	All products.[2]	Per cent.	Fuels.	Per cent.	Metallic.	Per cent.	All mine and quarry products.	Per cent.	Metallic.	Per cent.

Western	148,873,673	18.7	29,891,801	6.4	110,823,676	51.4	242,800,090	6.5	212,560,664	7.5

[1] Exclusive of Alaska and Hawaii.
[2] Includes structural, abrasive, and chemical materials, pigments, and miscellaneous minerals in addition to fuels and metalliferous minerals.

The North Atlantic states produced only 2.1 per cent of the ores, but the value of fuel amounted to 45.5 per cent and of manufactures to more than half of the total for the United States, indicating a concentration of manufactures to obtain the advantages incident to a liberal supply of fuel and a ready market.

The North Central states produced ore valued at $91,216,846, or 42.3 per cent of the total value of the ores, but the value of the fuels and manufactured products formed only 28.1 per cent of the total value for the United States. This tends to show that the ores were not used where they were mined, and that the mine operators were forced to take advantage of the transportation facilities to supply materials for the factories in the North Atlantic states. Of the ores obtained in these states, a value of $68,932,294 represented iron and copper from the mines of northern Michigan and Minnesota. The largest part of the freight transportation on the Great Lakes is on account of these mines. Transportation facilities here play an important part, the iron ores of Lake Superior being transported to the south Lake ports and to the centers of cheap fuel and iron consumption.

The value, $110,823,676, or 51.4 per cent of the total shown for the ores in the Western states, was composed very largely of the value of precious metals and copper, these minerals forming 67.9 and 29.1 per cent, respectively, of the total for the geographic division. The refined metal obtained from both of these minerals was sent elsewhere for manufacture.

The freight movement on the Great Lakes for 1902, as shown by the receipts at the Lake ports, aggregated 54,074,729 tons.[1] Of this, iron ore and mineral tonnage (not including coal) was 27,898,424 tons and coal 8,256,117 tons, making a total of 36,154,541 tons for mine products. This was 66.9 per cent of all freight.

[1] Department of Commerce and Labor, Bureau of Statistics, "Monthly Summary of Commerce and Finance of the United States," November 1 to February 28, 1902–3, page 1797.

The iron ore production of the upper Lake district, Michigan, Minnesota, and Wisconsin, was 27,056,861 tons, distributed as follows: Michigan, 11,135,215 tons; Minnesota, 15,137,650 tons; and Wisconsin, 783,996 tons. This was 76.1 per cent of the iron ore production of the United States. The copper shipments, though of great value, do not constitute a large tonnage item of the Lake traffic, as most of the ore is smelted at the mines and only the copper shipped. The copper product of northern Michigan for 1902 was 171,102,065 pounds, or 85,551 tons, but a large portion of this product was shipped as mineral to be smelted at Buffalo. The total copper shipments on the Great Lakes were 140,509 tons; this tonnage includes shipments of copper from the head of Lake Superior received from the West. The movement of iron ore on the Great Lakes is shown by the following table:

TABLE 70.—*Movement of iron ore on the Great Lakes: 1902.*

The chief use in manufactures of the various products of mines and quarries, and the aggregate value of the minerals and the manufactured products, so far as they can be reported separately, are shown in the following table:

TABLE 71.—MINE AND QUARRY PRODUCTS AND THE CHIEF MANUFACTURING INDUSTRIES UTILIZING SAME.

MINE AND QUARRY PRODUCTS: 1902.		MANUFACTURING INDUSTRIES: 1900.	
Character.	Value of product.	Character.	Value of product.
Total			$3,464,345,521
Metallic:			
Copper ore	$51,178,036	Bells; brass; brass and copper, rolled; brass castings and finishings; brassware; bronze castings; copper smelting and refining; electrical apparatus and supplies.	346,396,879
Gold and silver	82,482,052	Gold and silver, leaf and foil; gold and silver, reducing and refining, not from the ore; jewelry; pens, gold; plated and Britannia ware; silversmithing; silverware; watch cases.	95,676,333
Iron ore	65,465,321	Cutlery and edge tools; files; firearms; foundry and machine shop products; gas and oil stoves; gas machines and meters; hardware; hardware, saddlery; horseshoes, factory product; iron and steel; iron and steel bolts, nuts, washers, rivets, doors and shutters, forgings, nails and spikes, wrought pipes; ironwork, architectural and ornamental; ordnance and ordnance stores; pens, steel; registers, car fare and cash; safes and vaults; saws; scales and balances; screws, machine and wood; sewing machines and attachments; springs, steel, car, and carriage; steam fittings and heating apparatus; stencils and brands; tin and terne plate; tools; typewriters and supplies; vault lights and ventilators; wire; wirework, including wire rope and cable.	1,793,490,908
Lead and zinc ore	14,600,177	Babbitt metal and solder; paints (pigments); galvanizing; lead, bar, pipe, and sheet; lead, smelting and refining; type founding; zinc, smelting and refining.	222,398,643
Manganese ore	177,911	Iron and steel industries; pottery and glass; chemical and paint industries	(1)
Quicksilver	1,550,090	Amalgamation; manufacture of mineral pigments, chemicals, etc	(1)
Fuels:			
Coal, anthracite	76,173,586	Fuel (manufactures); coke; gas, illuminating and heating; coal-tar products	317,961,580
Coal, bituminous	290,858,483		
Natural gas	30,867,863	Fuel and lighting; gas carbon	(1)
Petroleum	71,397,739	Petroleum, refining	123,929,384
Structural materials:			
Cement	24,268,338	Lime and cement	28,689,135
Clay	2,061,072	Brick and tile; crucibles; pottery, terra cotta and fire-clay products	98,141,170
Limestones and dolomites	30,441,801	Lime (see cement); mantels, slate, marble, and marbleized; marble and stone work; monuments and tombstones; paving and paving materials; masonry, brick and stone; plastering and stuccowork.	368,958,899
Marble	5,044,182		
Sandstones and quartzites	10,601,171		
Siliceous crystalline rocks	18,257,944		
Slate	5,696,051		
Abrasive materials:			
Buhrstones and millstones	59,808	Millstones	75,922
Corundum and emery	104,605	Emery wheels	1,381,675
Crystalline quartz	43,085	Wood finishing and sandpaper	(1)
Garnet	132,820	Abrasives	(1)
Grindstones and pulpstones	667,431	Grindstones	1,088,909
Infusorial earth, tripoli, and pumice.	55,994	Cleansing and polishing preparations	(1)
Oilstones, whetstones, and scythestones.	113,968	Hones and whetstones	196,323
Chemical materials:			
Borax	2,383,614	Chemicals (boric acid); glass and pottery manufacture; terra cotta and fire-clay products (pottery).	(1)
Fluorspar	275,682	Glass; flux for iron furnaces; chemicals	(1)
Gypsum	2,089,341	Plastering and stuccowork (plaster of Paris and wall and cement plaster)	(1)
Phosphate rock	4,922,943	Fertilizers (rock phosphates)	38,565,297
Sulphur and pyrite	947,089	Chemicals (sulphuric acid); explosives (gunpowder)	12,615,795
Pigments:			
Barytes	203,154	Chemicals, paints (pigments)	6,643,215
Mineral pigments, crude	360,885		
Miscellaneous:			
Asbestos	46,200	Fireproofing, heat insulating, and noncombustible manufactures	(1)
Asphaltum and bituminous rock	236,728	Chemicals; paints and varnish; electric wire insulation; paving and paving materials	(1)
Bauxite	128,206	Aluminum; chemicals	[2] 1,920,000
Chrome ore	(1)	Furnace linings; hardening steel; chemicals	(1)
Feldspar	250,424	Pottery and tiles; wood filler; scouring soaps; glass manufactures	(1)
Flint	144,209		
Fuller's earth	98,144	Petroleum refining (clarifying oil)	(1)
Graphite	227,508	Graphite and graphite refining (crucibles, stove polish, paint, foundry facings, lead pencils, lubricants).[1]	429,173
Lithium ore	25,750	Chemicals (medicinal)	(1)
Magnesite	(1)	Furnace lining	(1)
Marl	12,741	Fertilizer	(1)
Mica	118,849	Axle grease; electrical apparatus and supplies (insulation); heat insulation; wall papers	(1)
Molybdenum	(1)	Hardening steel; chemicals	(1)
Monazite	64,160	Chemicals (rare earth salts for incandescent filaments)	(1)
Nickel and cobalt	(1)	Nickel: Hardening steel; alloys; coinage; electroplating Cobalt: Chemicals	(1)
Precious stones	328,450	Lapidary work	5,786,281
Rutile	(1)	Hardening steel; coloring porcelain; manufacture of artificial teeth	(1)
Silica sand	421,289	Glass, furnace, engine, and building sand	(1)
Talc and soapstone	1,138,167	Slabs: Hearthstones, furnace linings, etc Flour talc: Fireproof paints; electric insulation; heat insulation; furnace facings; lubricants; paper manufacture.	(1)
Tungsten	5,975	Hardening steel; chemicals	(1)
Uranium	48,125	Hardening steel; chemicals	(1)
Vanadium

XXI.

EXPORTS AND IMPORTS OF MINERALS.

Exports.—While the development of the export trade has been one of the leading features of industrial progress in the United States, the vast majority of mineral products of the country are subjected to manufacturing processes before they are sent out of the country, and therefore the products of the mines and quarries, as reported to the Census, form a very small proportion of the exports. The total exports of domestic merchandise for 1902, exclusive of gold and silver and phosphate rock, amounted to $1,349,493,266, and the exports of the products of mines, including crude mineral oils, amounted to $33,327,517, or only 2.5 per cent. The coining value of gold and the commercial value of silver produced during 1902, as based on the Census reports, and the production of gold and silver in Alaska, as estimated by the Director of the Mint, amounted to $102,695,557. Exclusive of coin the coining value of gold and the commercial value of silver exported was $70,419,846, the exports amounting to 68.6 per cent of the production. The classification followed by the Bureau of Statistics in compiling the statistics of exports does not correspond exactly with the classification of minerals adopted for the census of 1902. Their figures, however, may be used for the purpose of indicating the approximate amount of crude minerals exported. The following table presents the value of the exports of domestic merchandise, exclusive of gold and silver and phosphate rock, and the ratio of the exports of the products of mines to the total exports for each year from 1889 to 1902:

TABLE 72.—*Exports of domestic merchandise and products of mines, exclusive of gold and silver and phosphate rock: 1889 to 1902.*

[Compiled from annual reports of the Bureau of Statistics, on Commerce and Navigation of the United States, year ending June 30.]

YEAR ENDING JUNE 30—	Value of exports of domestic merchandise.	Value of exports of products of the mines, including crude mineral oils.	Per cent of products of mines to total exports.
1902	$1,349,593,266	$33,327,517	2.47
1901	1,455,414,413	34,159,482	2.35
1900	1,364,387,204	31,467,375	2.31
1899	1,197,941,331	22,166,283	1.85
1898	1,205,932,079	19,410,707	1.61
1897	1,027,001,674	20,804,573	2.03
1896	858,799,894	20,045,654	2.33
1895	787,651,337	18,509,814	2.35
1894	864,019,713	20,301,819	2.35
1893	826,877,918	19,794,502	2.39
1892	1,013,035,566	20,653,560	2.04
1891	870,054,467	22,020,428	2.53
1890	841,701,171	20,323,779	2.41
1889	729,213,079	19,866,557	2.72

The value of the exported products of mines has formed such a small proportion of the total exports that the statistics are instructive only in so far as they show the disposition of the different minerals. The following table presents the total value of each variety of the mining products, including crude petroleum oils, exported for each year since 1889:

TABLE 73.—VALUE OF EXPORTS OF PRODUCTS OF MINES, INCLUDING CRUDE MINERAL OILS: 1889 TO 1902.

[Compiled from annual reports of Bureau of Statistics, on Commerce and Navigation of the United States, year ending June 30.]

	1902	1901	1900	1899	1898	1897	1896
Total	$39,479,332	$39,815,162	$38,077,015	$28,197,101	$24,014,670	$26,972,982	$25,225,042

All other products of mining	259,859	182,555	60,570	36,944	43,310	50,480	89,244

[1] Not reported.
[2] Included in manufactures under the head of fertilizers, prior to 1899.
[3] Zinc ashes.
[4] Zinc, ore and oxide of.

With the exception of nickel and phosphate rock, the quantities exported formed only a small proportion of the mining products of the country. The value of the exports of nickel and phosphate rock in 1902 apparently exceeded the value of the total production of those minerals by $2,147,458. It is probable, therefore, that the classification adopted by the Bureau of Statistics included partially manufactured products, or other substances not included in the mining census, else the exports were composed in part of products mined during prior years.

The value of anthracite and bituminous coal formed more than a third of the value of the exports of the mining products in 1889 and in each year since. The $20,765,461 reported as the value of the coal exported in 1902 represents 6,971,184 tons; of this amount 4,732,185 tons, valued at $14,281,425, or 67.9 per cent of the quantity and 68.8 per cent of the value, were exported to Quebec, Ontario, Manitoba, etc.

Crude mineral oil was the next most important mineral product exported. There were 133,536,800 gallons of crude mineral oil exported during the year ending June 30, 1902, valued at $6,084,818. Of this total 89,733,032 gallons, valued at $4,272,144, or 67.2 per cent of the total quantity and 70.2 per cent of the value, were consigned to France; 10,844,913 gallons, valued at $550,694, were exported to Mexico; and 10,132,815 gallons, valued at $497,060, to Spain; leaving only 22,826,040 gallons, valued at $764,920, or 12.6 per cent, as the exports to all other countries.

Crude phosphate ranked third among the exports of mining products. The quantity exported for 1902 amounted to 747,672 tons, valued at $5,888,595. Of this total 372,035 tons, valued at $3,133,477, or 49.8 per cent of the quantity and 53.2 per cent of the value, were exported to the United Kingdom and Germany, and 375,637 tons, valued at $2,755,118, were exported to other countries.

There were 25,076 tons of copper ore exported, valued at $2,601,697; 13,875 tons, valued at $1,895,586, were consigned to the United Kingdom; and 11,139 tons, valued at $699,677, to Mexico, while only 62 tons, valued at $6,434, were shipped to other countries.

Imports.—The methods used in compiling the statistics of imports are also at variance with those followed by the census, and there are comparatively few products for which a satisfactory comparison of the imports and the production can be made, but the statistics for such products are presented in Table 74.

TABLE 74.—*Value of production and imports of certain comparable minerals: 1902.*

[Imports compiled from reports of the Bureau of Statistics on Commerce and Navigation of the United States, year ending December 31.]

MINERAL.	Production.	Imports for consumption.
Asbestos	$46,200	$762,432
Asphaltum and bituminous rock	236,728	492,658
Barytes	203,154	[1] 27,099
Bauxite	128,206	54,410
Borax	2,383,614	20,795
Buhrstones and millstones	59,808	16,158
Cement	24,268,338	2,556,061
Chrome ore	4,567	582,597
Clay	2,061,072	1,107,770
Coal, anthracite	76,173,586	792,469
Coal, bituminous	290,858,483	6,984,668
Copper ore	[2] 71,192,014	[3] 20,537,349
Corundum and emery	104,605	[4] 201,066
Flint	144,209	[5] 85,092
Gold and silver	[6] 92,911,013	[7] 55,688,883
Graphite	227,506	1,169,388
Grindstones and pulpstones	667,431	76,906
Gypsum	2,089,341	308,167
Infusorial earth, tripoli, and pumice	55,994	62,374
Iron ore	65,465,321	2,558,023
Lead and zinc	[8] 27,187,374	[9] 671,576
Magnesite	19,639	250,350
Marble	5,044,182	831,207
Mica	118,849	466,332
Mineral pigments, crude	360,885	195,868
Monazite	64,160	[10] 12
Natural gas	30,867,863	27,436
Nickel and cobalt	8,800	1,185,927
Oilstones, whetstones, and scythestones	113,968	56,456
Petroleum	71,397,739	176
Phosphate rock	4,922,943	388,479
Quicksilver	1,550,090	2,166
Stone (exclusive of marble)	64,996,967	51,657
Sulphur and pyrite	947,089	4,907,842
Talc and soapstone	1,138,167	35,366
Tungsten	5,975	7,046

[1] Baryta, carbonate and sulphate.
[2] Commercial value for copper contents of all ores mined.
[3] Value of imports of ore, regulus and black, and bars, ingots, and pigs.
[4] Emery grains and rock.
[5] Flint and flint stones.
[6] Commercial value of gold and silver contained in auriferous ores and placer bullion.
[7] Imports less foreign exports. Commercial value of gold and silver in ore and base bullion and bullion refined.
[8] Includes values for lead and zinc produced in gold, silver, and copper mines.
[9] Lead ore, dross, pigs, and bars; and zinc, in blocks or pigs.
[10] Monazite sand and thorite.

The minerals enumerated have been selected because the classifications by which they were designated in compiling the statistics of imports compare most nearly with the classifications used in compiling the census reports, but they should not be accepted as representing all minerals imported. Bismuth and lithographic stone were not produced in commercial quantities in the United States, and the entire consumption was dependent upon the imports.

The imports for a number of the minerals shown in Table 74 exceeded the production for 1902, and the conditions prevailing for each of them are summarized as follows:

Asbestos.—Practically the entire amount of asbestos consumed in the United States has been obtained from Canada. The imports for consumption in 1902 amounted to $762,432, as compared with a domestic

production of $46,200. Asbestos of suitable quality and in sufficient quantities to supply the demand has not been uncovered in this country.

Asphaltum and bituminous rock.—While there has been a growing increase in the production of asphaltum and bituminous rock in the United States, the value of the imports for consumption for 1902 exceeded the value of the domestic production by $255,930. The domestic production was crude material, and it is probable that the imports were of a more highly finished character. The material is obtained in an almost pure form from Pitch Lake, in the island of Trinidad, where the cost of production is reduced to a minimum. The quantity imported from this source during the year ending June 30, 1902, was valued at $329,819. The asphaltum imported from Barbados possesses peculiar qualities which make it especially adaptable for the manufacture of varnishes and the insulation of electric cables.

Chrome ore.—Practically all of the chrome ore consumed in the United States was imported. The deposits in the United States are not conveniently located for development and can not compete with the low price of the foreign ore.

Corundum and emery.—The value of the imports of corundum and emery was almost twice as great as the value of the domestic production. The excess of the imports over the production was due chiefly to the fact that the largest domestic deposits are not conveniently located for transportation facilities and can not compete with the large deposits of Canadian corundum that can be more conveniently worked; or the production of Turkish emery, which is produced at a considerably lower cost and imported into the United States as ballast. Artificial corundum, moreover, is also produced in large quantities and will undoubtedly affect the production of the natural material.

Graphite.—While graphite has been developed in a number of different localities throughout the United States, the production still falls far short of the demand, which has increased with the development of the mechanical and electrical industries. Graphite is also being successfully produced by artificial means. The imports, however, are still many times in excess of the domestic production.

Infusorial earth, tripoli, and pumice.—The value of the imports of these minerals exceeded the domestic production by $6,380. This increase was due entirely to the imports of pumice, for this mineral has been found and quarried in the United States in comparatively insignificant quantities. The imports were obtained almost entirely from the island of Lipari, north of Sicily, and were shipped largely as ballast.

Magnesite.—The entire domestic production of magnesite was obtained from mines in the state of California, which apparently are not able to supply the market. No other deposits appear to have been discovered. The imports were obtained almost entirely from Greece and Austria.

Mica.—While this mineral is found in a number of the states and exists in considerable quantities in different localities, the individual deposits have not been developed to a great extent, and the quality is inferior to that of the imported variety which is obtained largely from Canada and India. The good variety of mica obtained from the deposits in India and the cheap labor there enables it to be produced and delivered in the United States in sufficient quantities to almost entirely supply the market.

Nickel and cobalt.—Practically all of the nickel and cobalt consumed in the United States is obtained from Canada, where the deposits are extensive and cheaply mined. Both minerals have been found and mined in various localities in the United States, sometimes in connection with lead ore, but they have not been produced in quantities sufficient to supply the market, because, in part, of the moderate price which has prevailed for nickel.

Sulphur and pyrite.—The excess of the imports over the production of sulphur is not due apparently to its scarcity in the United States, but to the immense deposits of pure sulphur found in Sicily, which are worked by cheap labor. The imports of pyrite more than doubled the production.

Tungsten.—The imports of this mineral exceeded the comparatively small production by only $1,071. The domestic production has been obtained largely in connection with other minerals.

Of the other minerals enumerated in Table 74 the following show the largest amounts imported during the year 1902, the minerals being considered in the order in which they appear in the table.

Cement.—The production of cement reported by the census is confined to the manufacture of cement at and in connection with the operation of limestone quarries. The total production for 1902, as reported by the United States Geological Survey, was valued at $25,366,380. The imports, therefore, formed a comparatively small percentage of the total consumption. There were 423,844,160 pounds of Roman, Portland, and other hydraulic cement imported during the year ending June 30, 1902, and these were valued at $1,478,452. Of these imports 227,056,720 pounds, valued at $834,555, came from Germany; all other countries sent 196,787,440 pounds, or 46.4 per cent, of the quantity, valued at $643,897, or 43.6 per cent of the total.

Clay.—As shown by Table 74, the value of the clay imported for consumption was more than half as great as the value of the domestic production. Common blue clay, used for the manufacture of crucibles, was obtained very largely from Germany. The imports from that country for the year ending June 30, 1902, were valued at $59,492, as compared with $13,603 re-

ported for all other countries. Other clay, including China clay, or kaolin, came largely from the United Kingdom and Germany, the imports from these countries amounting to $1,122,647, or 92.4 per cent of the total for other clay.

Coal.—While the imports of coal form a very small proportion of the consumption, nevertheless considerable quantities of bituminous coal were imported during the year 1902, the imports being stimulated to some extent by the shortage in the production of anthracite coal. The imports from British Columbia, Nova Scotia, and New Brunswick for the year ending June 30 were valued at $3,904,526, forming 73.5 per cent of the total imports. Including anthracite the imports from all other countries amounted to $1,407,882, or 26.5 per cent of the total.

Copper.—The imports for consumption of copper during the calendar year 1902 were valued at $20,537,349, the amount being about one-third as great as the production; this mineral is imported largely from Mexico. The imports from that country for the year ending June 30, 1902, were valued at $9,934,097, or 70.9 per cent of all copper imported.

Gold and silver.—Gold and silver ore and bullion is the most important class of imports, the amount—$55,688,883—reported for 1902 constituting 70.7 per cent of the total for the principal minerals imported, as shown by Table 74. Of this aggregate the value of gold was $32,582,221, or 41.4 per cent, and the value of silver was $23,106,662, or 29.3 per cent. Of the silver approximately 85 per cent was imported from Mexico. Of the gold about 30 per cent was obtained from Quebec, Ontario, etc., and about 27 per cent from Mexico.

Iron ore.—The imports for consumption of iron ore during the calendar year 1902 were valued at $2,558,023. Of the imports for the year ending June 30 iron ore valued at $1,109,205, or 46.9 per cent, was obtained from Cuba; a value of $677,131, or 28.7 per cent, from Quebec, Ontario, Manitoba, etc., and $406,662, or 17.2 per cent, from Spain.

Lead and zinc.—The imports of lead ores came almost entirely from Mexico and British Columbia, the amount received from these countries for the year ending June 30, 1902, being valued at $4,401,390, or 97.9 per cent of the total.

The value of the minerals imported during 1902 was more than twice as great as the value of the exports of similar products. In a number of instances the imports bear an important relationship to the consumption, and the statistics are worthy of more detailed consideration. To assist in such an analysis Table 75 is presented, which gives the value of all the minerals or mineral products, as classified by the Bureau of Statistics, that have been imported for consumption each year from 1889 to 1902. Some of them are not included in the preceding comparative table.

TABLE 75.—IMPORTS FOR

[From reports of the Bureau of Statistics,

	MINERAL.	1902	1901	1900	1899
1	Agate, unmanufactured	$1,379	$960	$635	$195
2	Asbestos, manufactured	25,819	26,209	16,314	9,559
3	Asbestos, unmanufactured	752,125	427,333	292,879	296,508
4	Asphaltum or bitumen, crude	432,005	501,310	357,938	226,635
5	Asphaltum and bitumen, dried or advanced	38,760	42,611	43,196	18,557
6	Asphaltum, manufactures of	4,949	1,935	1,656	1,575
7	Asphaltum and bitumen, crude or dried				
8	Asphaltum and bitumen, limestone rock asphalt containing not more than 15 per cent of bitumen.	21,617	52,529	42,085	39,761
9	Baryta, carbonate of, or witherite	15,870	15,208	15,681	15,552
10	Baryta, sulphate of, or barytes, including barytes earth unmanufactured	14,453	6,959	7,886	1,298
11	Bauxite or terra alba, aluminous	52,245	63,597	11,413	14,168
12	Brazilian pebble		697		877
13	Borax	26,865	18,291	5,960	2,755
14	Borax, refined				
15	Borax, borates of lime or soda or other borate material not otherwise provided for	10,746	7,491	3,594	24,903
16	Borax, borate of lime				
17	Borax, crude, or borate of soda				
18	Cement, Roman, Portland, and other hydraulic, in barrels, sacks, or other packages	1,443,900	2,164,556	3,194,897	2,694,313
19	Cement, Roman, Portland, and other hydraulic; other	52,776	71,928	47,587	43,783
20	Cement, Roman, Portland, and all other				
21	Cement, Portland, Roman, and other hydraulic, in bulk			6	
22	Chromate of iron or chromic ore	525,611	214,762	378,101	264,376
23	Clay, china clay or kaolin	849,314	701,791	694,280	599,650
24	Clay, common blue, in casks	73,100	67,763	111,762	76,014
25	Clay, unwrought or unmanufactured, not specially provided for	146,725	144,050	131,478	101,331
26	Clay, wrought or manufactured, not specially provided for	65,177	58,511	40,435	27,871
27	Clay, all other not specially provided for	13		136	62
28	Coal, anthracite	2,006	6	628	2,686
29	Coal, bituminous and shale	4,541,338	4,585,335	4,022,802	3,479,931
30	Coal, slack or culm, such as will pass through a half-inch screen	757,392	787,515	440,046	109,331
31	Coal, coke	359,438	309,614	232,947	171,995
32	Cobalt and cobalt ore and zaffer	27,237	11,863	7,414	10,986
33	Cobalt, oxide of	137,959	111,740	72,072	67,442
34	Copper ore	2,556,687	2,944,791	1,639,352	608,399
35	Copper, regulus of, and black or coarse copper, and copper cement	11,275,576	7,471,649	1,002,978	586,430
36	Emery ore	137,695	288,424	162,056	138,891
37	Emery, grains and ground, pulverized, refined, or manufactures of emery	55,870	30,509	28,524	28,038
38	Emery, grains and ground, pulverized or refined				
39	Emery, fillet				
40	Feldspar				
41	Fuller's earth, unwrought and unmanufactured	21,142	16,006	19,985	21,560
42	Fuller's earth, wrought or manufactured	68,160	55,450	41,523	54,772
43	Gold ore and bullion [1]	34,263,560	37,238,149	23,499,557	35,740,111
44	Hones and whetstones	59,617	51,333	40,128	30,916
45	Iridium	22,470	6,072	5,053	6,561
46	Iron ore, ores including manganiferous iron ore; also dross or residuum from burnt pyrites	2,333,123	1,131,765	1,497,713	403,298
47	Iron ore, basic slag	9,868	6,398	999	
48	Iron ore, all other ore				
49	Lead, lead-bearing ore of all kinds	224,416	247,627	167,937	185,872
50	Lead, base bullion	48,041	78,845	32,694	21,615
51	Lead contained in silver ore				
52	Lead contained in all other ore and dross				
53	Magnesite, crude or calcined, not purified (purified for 1902)	312,645	281,901	330,102	158,267
54	Magnesite, or native mineral carbonate of magnesia				
55	Manganese, ore and oxide of	1,784,120	1,163,971	2,695,211	876,478
56	Manganese, oxide of				
57	Manganese ore				
58	Mica, unmanufactured or rough trimmed only	361,436	301,740	263,472	182,278
59	Mica				
60	Mica, cut or trimmed	42,769	30,619	32,783	40,481
61	Mica and mica waste				
	Mineral paints:				
62	Brown, Spanish, Indian red, and colcothar or oxide of iron	67,142	66,251	72,860	56,484
63	Brown, Spanish, Indian red, and colcothar or oxide of iron, and Vandyke Cassel earth or Cassel brown.				
64	Brown, Vandyke Cassel earth or Cassel brown	311			
	Ocher and ochery earths, not specially provided for—				
65	Crude, not powdered, washed, or pulverized	600	337	6,423	1,155
66	Powdered, washed, or pulverized	104,656	54,384	63,278	55,686
67	Ocher and ochery earths, dry				
	Sienna and sienna earths, not specially provided for—				
68	Crude, not powdered, washed, or pulverized	10,955	4,777	950	3,489
69	Powdered, washed, or pulverized	13,480	8,878	16,196	7,724
70	Sienna and sienna earths, dry				
	Umber and umber earths, not specially provided for—				
71	Crude, not powdered, washed, or pulverized	6,497	8,103	8,517	5,488
72	Powdered, washed, or pulverized	4,375	5,103	4,176	5,216
73	Umber and umber earths, dry				
74	Minerals, crude, or not advanced in condition by refining or grinding or other process of manufacture, not specially provided for.	112,886	73,715	57,439	62,421
75	Minerals, not dutiable, advanced in value or condition by refining or grinding or other process of manufacture, not specially provided for.	14,690	5,383	24,087	18,893
76	Mineral substances in a crude state, not specially provided for				

[1] Imports less foreign exports.

CONSUMPTION: 1889 TO 1902.

on Commerce and Navigation in the United States, year ending June 30.]

CHAPTER III.

ELECTRICITY IN MINING.

By Thomas Commerford Martin.

The mining industry to-day constitutes one of the most important fields for the application of electric current. There is hardly a country in the world and hardly any department of mining in which electrical appliances are not employed, and in many instances the installation and equipment are of a most extensive character. Indeed, the subject has become so important as to create a literature and a technology of its own, for many of the problems involved are such as do not arise in connection with other work. Hence a brief technical review of the situation can not but prove of interest, especially as the whole tendency of the time is to develop mining industries along electrical lines, and in fact to employ electricity continuously from the very first contact with the ore to the stage at which the finished product is ready for the market. It is proposed, however, to limit the present treatment of the subject to electric mining, as both electro-metallurgy and electro-chemistry are distinct fields of technical work, dealing with manufactured material rather than with the cruder and more primitive processes of winning the minerals from the soil. In its early stages electric lighting was applied to mine work, and this development was followed by the use of electric locomotives for traction as a substitute for human or brute power. Of late years the electric motor has been utilized for all classes of work—drilling, coal cutting, hoisting, pumping, ventilating, etc. The use of electric explosives has long been familiar to every miner, and more recently the telephone has become a familiar adjunct for purposes of intercommunication.

In the United States, as elsewhere, the introduction of electrical mining apparatus has been greatly stimulated of late years by the high degree of perfection attained in the art of power transmission. A great many mines and mining camps in regions where fuel was either very costly or difficult to obtain have been brought within the range of profitable working through the utilization of some distant waterpower. The single and polyphase alternating current, with its flexibility and high range of pressure, has made it possible to transmit power from water courses across valleys and over mountain ranges for scores of miles, so that to-day large areas, which but for the assistance of electricity would have remained neglected, because unavailable, are being worked. The profitableness of American mines and the sources of national wealth have thus been enormously increased.

The practical use of electricity involves a great many questions, of the nature of which some idea may be formed from the report recently issued in England by a departmental committee appointed by the British Home Secretary to consider and report on the subject. As the result of its investigation the committee laid down four general principles which, it considered, should govern the appointment of electrically equipped mines. These points may be summed up as follows:

1. The electric plant should always be treated as a source of potential danger.
2. The plant should be of thoroughly good quality and so designed as to insure immunity from danger by shock or fire, and periodical tests should be made to ascertain that this state of efficiency is being maintained.
3. All the electrical apparatus should be under the charge of a competent person.
4. All electrical apparatus which might be used where there was a possibility of danger arising from the presence of mine gas should be inclosed so as to prevent such gas from being fired by the sparking of the apparatus, and when any machine is working every precaution should be taken to detect the existence of danger, and on the presence of gas being noticed such machinery should be immediately stopped.

Some of these points seem obvious, yet they have frequently been disregarded. With regard to the first and second, the committee pointed out the fact that under the peculiar conditions existing in mines no absolutely safe limit of voltage or of pressure of current could be stated. The committee decided, however, on grounds already recognized in Germany that, provided all reasonable safeguards were adopted, a fairly high pressure had advantages, even from the point of view of safety, over a uniformly low pressure. The standard adopted by the board of trade as to voltage in consumption circuits is, therefore, 650 volts. Under certain conditions voltages as high as 3,000 volts are available for transmission purposes.

30223—04——10

As to the working of electric coal cutting machinery in places subject to fire damp, the committee decided, largely as a result of experiments made, that it was necessary to inclose the entire motor in a flame-tight cover. The committee adopted the view that all permitted explosives should be fired by electricity, and that the armored sheath or covering of all protected cable should be connected to "earth"—i. e., grounded.

Table 1 shows the number of mines in the United States reported as owning or renting electric power in 1902, together with the horsepower reported, for each group of minerals.

TABLE 1.—*Electric power, by minerals: 1902.*

Siliceous crystalline rocks	27	913	18	442	9	471
Slate	7	225	2	30	5	195
Sulphur and pyrite	2	80	2	80	.....	.....
Talc and soapstone	1	225	1	225	.....	.....

It will be seen from this table that the number of mines reporting electric power was 802, with a total of 154,050 horsepower. By far the larger proportion of these—namely, 688, with a total of 130,494 horsepower—operated their own plants. There were 131 mines, with a total of 23,556 horsepower, which rented power, but of these mines 17 owned power also. It will be gathered from these figures that the 130,494 horsepower, even if it represents the total current-generating capacity, shows a considerable application of electric power; but it should probably be doubled in order to ascertain the capacity of motors installed and using such current. It is a fact well known in electrical plants that motor capacity far beyond the actual current capacity of the generating plant can be installed, for the reason that the consumption of current is variable and intermittent, it being highly improbable that all the consuming apparatus will take full current from the lines at the same time. It is assumable, however, although the fact is not brought out at all in the table, that in a great many instances these plants furnish also considerable current for lighting purposes. With regard to the rented power, it is probable that it is employed almost altogether to drive motors, a very small proportion of it representing electric lighting. Mines in which the operations are so small as not to necessitate the installation of a separate plant are, it is assumed, operated largely by single shifts or during daylight hours; so that while some lighting would be needed, the consumption of current would be quite small in proportion to the consumption for hoists, pumps, and other motor-driven mechanism.

It will be noted that four-fifths of the electric power reported was concentrated in three industries—coal mining, cement working, and the gold and silver industry. By far the largest item is that of bituminous coal mining, such mines, numbering 309, reporting electric power with a total of 68,139 horsepower; and these figures must be supplemented by those for anthracite coal mining, with 17 plants, reporting 5,755 horsepower. It will be seen that those two groups alone represent nearly one-half of the total horsepower. The figures for gold and silver are combined, and the table shows 292 plants reporting, with a total of 46,472 horsepower. The other category is that of cement mining. There were 31 cement mines reporting electric power, with a total of 20,862 horsepower.

It will be observed that these various mines differ considerably as to the magnitude of installation. In the gold and silver mines the plants have an average capacity of about 160 horsepower; in the coal mines the average capacity is 227 horsepower; in the cement mine works the average capacity is greater than for any other kind of mines—about 675 horsepower. The other items in the table, while interesting, do not call for any particular comment.

Power generation and transmission.—Electric current for mining purposes is usually obtained in one of two ways, depending somewhat upon the nature of the mine in the first place, and secondly upon the environment. In coal mining regions it is natural that each mine should draw upon its own fuel resources for power, the plant being stationed at the pit mouth; but even in such cases, where there is a group of mines it is sometimes found convenient to concentrate the power-generating apparatus, transmitting the current to a distance. This has been done in an even more comprehensive way in western mining fields, one steam plant which utilizes coal delivering its energy to mines no less than 26 miles distant, in districts where waterpower is not available. Where the generating plant is at the mouth of the mine it is customary to employ apparatus producing low tension direct current; but where longer distances are involved the alternating current has been resorted to, in the same manner as in central electric lighting and railway plants. The current is generated at high potential by polyphase dynamos and transmitted to substa-

PLATE I.—LONG DISTANCE ELECTRIC TRANSMISSION IN CALIFORNIA.

tions, where it is lowered in pressure and converted into direct current for use.

One of the first plants of this kind for a mine haulage system was installed at Ehrenfeld, Pa. The haulage in this mine was accomplished by rope driving and mules until the main heading, which should eventually extend 5 miles underground, was nearly 2 miles long. This method was then replaced by an electric system embodying the generation of a 3-phase, 25-cycle, 5,600-volt alternating current near the pit mouth. This current is transmitted by insulated cables to a substation in the mine itself, near the center of the actual operations and about 9,000 feet from the power house. Through the intervention of static transformers and a rotary converter, direct current at 275 volts is then delivered to the haulage circuits.

In the Tug River field, near Welch, W. Va., is another plant of the same kind by which three mines are operated, alternating current induction motors being employed for driving coal crushers and conveyors and direct current for the other mine operations.

An interesting variation of this plan is that embodied in the plant constructed for the Raton Coal and Coke Company, at Blossburg, N. Mex. When built, in 1897, the coke plant included some seventy-five 3-foot ovens, in double banks. In the center was erected a large battery of boilers, to which the waste gases from the coal are conducted through central flues; the gas thus made available is employed to drive gas engines and dynamos furnishing power for the hauling plant both inside and outside of the mine. About a mile and a half from the coke ovens is situated the washing and crushing plant, with a capacity of 800 tons in ten hours. All the machinery from tipple to mine opening is driven by electric motors, a trolley line with electric locomotives bringing the pit cars from the main entry to the tipple. This idea of the utilization of waste gas in coke fields and blast furnaces has of late occupied considerable thought and attention on the part of mechanical and mining engineers, and important developments are resulting from the employment of electricity as a means of lessening waste.

In most mining districts, however, the work is intermittent, machinery is widely scattered in places difficult of access, fuel is expensive, and the economical use of steam is not possible. Compressed air, as a means of transmitting power, is handicapped by loss in the compressor and the piping, and is limited to short distances and to the operation of apparatus requiring power regardless of cost. In this connection, reference may be made to the tests reported by Mr. Lewis Searing, in 1896, with electricity and compressed air, in a mine situated at Rouse, Colo., at an altitude of 6,000 feet. The actual results obtained with the two plants show that the work of pumping, which in the case of compressed air required 312 horsepower and 8 boilers, could be done by electricity with but 56 horsepower and 1 boiler. This, of course, is an extreme case, but it indicates the difficulties attendant upon the use of compressed air at such altitudes.

Under the modern conditions of power transmission from waterfalls, etc., electricity has shown itself to be largely independent of distances, so that, as was pointed out by Mr. F. O. Blackwell, before the American Institute of Mining Engineers, in February, 1903, a given amount of power can be delivered either 528 feet away, at 100 volts, or 50 miles away at 50,000 volts, with the same total amount of copper per horsepower and exactly the same loss of power in the transmission circuit. With proper choice of potential and system, this loss need not exceed 10 per cent, even when the current is carried as far as 150 miles.

So much has been done in the matter of power transmission for mining purposes that it is difficult to pick out any specific case as thoroughly typical. But it would be hard to find an instance more notable than that of the Standard and Bay Counties Power Companies, in California. These, consolidating other systems, have a remarkable network of circuits of which one of the largest begins at Colgate, in the foothills of the Sierras, on the North Yuba river, a second at Folsom City, a third at Electra, and a fourth at De Sabla. From Colgate to Oakland, where the Bay Counties Company's line ends, is a distance of 152 miles; from Oakland to San Francisco, by the Standard Company's line, is 70 miles. The tying in at Oakland thus gives a transmission circuit of 232 miles from the latest plant at De Sabla, beyond Colgate, around San Francisco bay and through San Jose to San Francisco. Over the network thus represented, which embraces no fewer than 16 counties, within whose borders lie one-half of the population and three-fourths of the total assessed valuation of property of the state, several thousand horsepower is delivered daily. Alternating current is distributed to substations at pressures of 40,000 to 60,000 volts, and there manipulated and rectified for delivery to establishments engaged in a variety of industries, including a large number of mining plants.

The Bay Counties system is in fact an outcome of earlier mining enterprises, one of which was undertaken for Nevada county to supply the mines there with power. In like manner the Standard system is an outgrowth of work started thirty years ago by the Blue Lakes Water Company, when a ditch system considerably more than 80 miles in length was constructed for the purpose of furnishing water to the mines in Amador county. For a long period this company was very prosperous, but with the decline of mining in that section of the mother lode and the complete abandonment of hydraulic mining the property became much less profitable. At this stage it was taken up again by Prince Poniatowski, to be developed for the purpose of distributing electric power to mines and thus lessening the cost of their operation.

The plant at Colgate had an initial equipment of 15,000 horsepower in 3-phase alternating-current dynamos, situated in a power house at the foot of a hill 1,500 feet high. Water for driving the turbines is brought to this plant through a timber flume over 7 miles long draining 500 miles of watershed, and with a capacity of 33,000 cubic feet of water per minute. This water, received in the reservoir near the crest of the hill, falls with 700-foot head upon the turbines under a pressure of 304 pounds per square inch. The current from the generators is delivered at a pressure of 2,400 volts to step-up transformers, which put it on the circuit at a pressure of 40,000 to 60,000 volts. These transmission circuits, each of three wires, are carried on lofty poles of Oregon cedar and are in duplicate, one set consisting of hard-drawn copper wire and the other of aluminum. At the Karquines straits the circuit crosses in one span of 4,448 feet of sagging steel cable 200 feet above tide water and held up by enormous steel lattice towers. The system has in operation about 700 miles of line at 50,000 volts, 70 miles at 40,000, and a great many miles at 23,000, 16,000, 10,000, and 5,000 volts. It is stated with regard to the efficiency of the transmission that 1,000 horsepower at the Colgate water wheels nets roughly about 750 available horsepower in San Francisco, 222 miles away, the loss being 6 per cent in the generators, 2 per cent in the step-up transformers, 2 per cent in the step-down transformers, and 15 per cent in line losses, etc. This does not represent the general efficiency of the whole system, because there are a great many branches and tap circuits, to mines, etc., but it is understood that the results attained by the system as a whole are such as to have stimulated the construction of similar plants, one of which has been erected for mining purposes, with American apparatus, at the Cauvery Falls, Madras, India. Such a plant as this is a sufficient exemplification of the possibilities involved in electrical power transmission for mining purposes, utilizing the energy of falling water.

Such transmission will again be referred to incidentally in connection with certain utilizations, but before closing this section reference should be made to the important work undertaken for electric power distribution from coal mines in England and Wales, a country with cheap coal but very little available water-power. Since 1901 there have been established a number of plants and companies for long distance transmission, based upon coal mining and intended largely for mining purposes. In fact, one of these, at Newcastle-upon-Tyne, covering a strip of territory in the vicinity of the Tyne river, began on a small scale in 1898; it was greatly enlarged in 1902. One in southern Wales covers the coal and iron field of that section. One in Lancashire covers the coal field of that county, extending on the west to the Irish sea. One in the county of Durham covers 250 square miles of coal territory, extending to the North sea. One in adjacent territory, including the Cleveland iron field in Yorkshire, covers an area of 820 square miles, while one in southern Yorkshire covers 1,800 square miles. One in the counties of Leicestershire and Warwickshire covers 1,699 square miles, while one in the county of Cornwall, particularly designed to revive the decaying mining industries of that famous old tin region, covers 1,356 square miles. Another system in Derbyshire and Nottinghamshire deals with an area of 1,500 square miles.

A few details may be given as illustrative of the extensiveness of the English enterprises, some of which are now actually in operation. Within the area of Derbyshire and Nottinghamshire—containing some of the largest coal fields in the world—are electric power companies with a capital of about $9,000,000. There are within it 564 individual works of importance, of which 159 are coal pits, and no fewer than 400 firms, representing a capital of about $100,000,000, supported the enabling bill when passing through Parliament. It was proposed at first to have for this area four large generating stations, with a total capacity of 60,000 horsepower, but in 1903 the applications for power so far exceeded the estimates that it was even then proposed to enlarge at least two of the generating stations. While in the individual mines and mining enterprises the largest individual dynamo or engine unit is 200 horsepower, the smallest unit for this system is one of 3,000 horsepower. The numerous collieries in the region are counted upon as the principal customers for this supply of current, and, taking as a basis the fact that about 7 per cent of the coal mined is consumed in obtaining the 93 per cent sold, it is estimated that by the use of electricity in mines under these new conditions, in connection with the various purposes of hoisting, traction, pumping, ventilating, etc., 10,000,000 tons of coal can be saved annually. The operations of the power companies at Newcastle-upon-Tyne have shown that power can be delivered to large works in the vicinity at a rate slightly exceeding 2 cents per kilowatt-hour unit—that is, at a rate of about 1½ cents per horsepower per hour. Elsewhere in England and Wales the collieries themselves have demonstrated the efficiency of electric power transmission, as, for example, in the case of the Tredegar Iron and Coal Company, in Monmouthshire, Wales, whose plant is the largest of the kind for individual mining enterprise in England or Wales. Two 300-horsepower engines direct connected to 3-phase generators at one set of mines supply current over pole line transmission circuits at 2,000 volts to other mines about a mile and a quarter away. Both electric haulage and electric pumping are features of this installation, and at the time of the last report it was noted that, although these mines were peculiarly subject to fire damp, no accident of any kind had happened because of the special precautions taken to insure safety.

One installation which will serve to exemplify the latest general features of current transmission, as well as economical generation at the mine, is furnished by the central power plant of 2,000 horsepower installed by the coal mining department of the Delaware, Lackawanna and Western Railroad Company in Scranton, Pa., to supply current for drills, locomotives, hoists, pumps, lights, etc., in the Diamond, Hampton, Brisbin, Hyde Park, and Sloan mines. The alternating current is transmitted at a pressure of 2,300 volts, and reduced at substations at the various mines by step-down transformers and rotary converters to direct current, which is employed in the mines, supplemented by two alternating induction motors of 800 horsepower each in a water-hoisting shaft 600 feet from the power plant. The greatest distance to which power is transmitted is about 15,000 feet, to the Diamond mine, which takes about 175 horsepower. The current is furnished to some 14 electric locomotives in the various mines, ranging from 6½ to 13 tons, and to a 120-horsepower electric hoist. Added to the previous plant of the company the generating apparatus represents a capacity of about 5,000 horsepower, supplying current to 45 electric locomotives, 14 motor-driven pumps, 18 operative hoists, 14 motors in a breaker, and 1 electric drill, or a total of 6,820 horsepower in consumption capacity. It has been decided to increase the plant so as to transmit current 3 miles, to supply power for operating 25 direct-current motors at the Delaware, Lackawanna and Western locomotive repair shops, etc., 100 arc lamps for lighting freight yards, machine shops, etc., and 1,500 incandescent lights for a passenger station, freight office, and roundhouse. The most notable thing about this new plant is the fact that the additions to which special reference has been made employ the latest form of steam equipment in the shape of steam turbines instead of the more familiar reciprocating steam engine. These turbines, two of which were already installed at the time of the compilation of these notes, are each of 500 kilowatts, or about 675 horsepower capacity, and will carry 50 per cent overload for two hours, or 100 per cent overload momentarily, without injurious heating of the generator.

Coal cutting machinery.—Electric coal cutters constitute one of the largest classes of mining machinery employing electric current. The considerable increase during recent years in the proportion of machine mining as compared with that of pick mining is doubtless due to the adoption of these machines. According to the report of Mr. E. W. Parker on the production of coal, published by the United States Geological Survey, the number of coal mining machines in use in this country in 1898 was 2,622, but in 1902 it had increased to 5,418; all of these were employed in bituminous coal mines.[1] The increase during recent years is attested to also by the fact that while in 1891 the mining machines of the country produced slightly less than 7 per cent of the total product of bituminous coal, in 1902 they produced somewhat over 26 per cent.

The older form of machine is of the pick or puncher type run by compressed air, but of late years the chain form driven by electricity has rapidly come into use. Of the 5,418 machines in use in 1902, 58.8 per cent were of the compressed air or pick type, while the other 41.2 per cent were electric or chain machines. Of the 2,233 chain machines, almost all were of breast form, only 51 being of the long-wall style.

Some interesting details with regard to the introduction and utilization of electric coal cutting machinery were recently made public by Mr. S. B. Belden, who is connected with one of the largest concerns manufacturing such apparatus. Speaking of the first chain machines, designed by Mr. J. H. Jeffrey, Mr. Belden stated that their height precluded the possibility of operating them in thin coal, and that for several years no attempt was made to build a machine designed specially for such work. Even when the chain machine was an established success, it was a question whether a machine weighing more than a ton could be employed in coal ranging between 32 and 36 inches in thickness. But after these large machines had proved successful in thick veins they began to be used in lower coal until the minimum thickness of the vein had been reached.

Gradual evolution has produced a smaller and lighter machine, so that there is now in use one which has a height of only 18 inches, or, with the moving truck, of 28 inches, and a weight of only about 2,500 pounds. As this machine rests upon a wide flat shoe board it can easily be moved along the face of the coal by the operator and his helper. A brief description of the apparatus will be of interest. On an outside frame, consisting of two steel channel bars and two angle irons riveted to steel crossties, rests a sliding frame consisting of a heavy channel or center rail, to which is bolted the cutter head. The cutter head is made entirely of two milled steel plates, which bolt together, forming the front guide for the cutter chain. This chain, which is made of solid cast steel links connected by drop-forge straps, is carried around idlers or sprockets placed at each end of the cutter head and along the chain guides at the side to the rear of the machine, where it engages with and receives its power from a third sprocket, under the motor. The electric motor, which is of ironclad multipolar type, rests upon a steel carriage, which forms the bearing for the main shaft. The thin vein machine is equipped with a self-propelling truck, the motor which operates the machine being also geared to the truck axles. A reversing switch is provided, so that the truck can travel in either direction, and when the machine has reached its stopping point, either forward or backward, it is checked by an automatic cut-off. The return travel is made in about one-fourth of the time required to make the cut.

[1] United States Geological Survey, "Mineral Resources of the United States," 1902, pages 325 to 327.

Where the grades are heavy the truck is of advantage, and where the room lies to the dip it obviates the necessity of brushing down the roof for the entry of mules.

It is stated by Mr. Belden that many mines having only 28 to 30 inches of coal are being operated entirely with thin vein machines, and that a fair average for such machines is the cutting of at least 50 tons of coal per eight-hour shift. As nearly all of these machines are operated by two shifts, the output of a machine working in such a vein can be reckoned at 100 tons per day. Many small mines have a daily output of only 400 tons, and it is estimated that $10,000 will cover the necessary expenditure for an electric equipment of about 100 horsepower, affording sufficient power to keep four such machines in simultaneous operation, besides furnishing power for lights, pumping, ventilation, etc.

According to the schedule adopted in No. 8 vein of Ohio coal, the cost of pick mining in rooms is 90 cents per ton, while the cost of machine mining in rooms is 11 cents, with 52½ cents for loading after machines in rooms. This shows a saving through the substitution of machine mining for pick mining of 26½ cents per ton. A liberal allowance for operation and depreciation would leave a net saving of over 13 cents per ton, and the four machines should produce at least 75,000 tons per year. Numerous data received from various mining sections bearing upon the cost of operating such apparatus per ton of coal give figures ranging from one-tenth of 1 cent up to 2 cents, according to the hardness of the coal and the degree of care and skill observed in operating.

Discussing the subject in an admirable article on coal-cutting machinery, Mr. E. W. Parker expressed the opinion that the evolution of the chain machine was one of the most notable steps—and practically the final step—in the development of a successful mining machine. The speed with which the chain machine can do its work seems incredible. After the machine has been placed in position an average period of only five minutes is required to make a cut 44 inches wide, 4½ or 5 inches high, and 6 feet deep, and then withdraw the cutting frame. In fact, for one of these machines there is claimed a record of cutting 1,700 square feet in nine and one-half hours. This would mean that about seven and one-half minutes were required for each cut 44 inches wide and 6 feet deep, including the moving and setting of the machine. An average much lower than this would attest the efficiency and utility of the apparatus.

As to the advantages of the modern chain machine over the earlier forms of pick machine, the former bases its claims upon the rapidity with which the work is done, the very small amount of slack coal that is made in the cutting process, and the fact that the runner is not subjected to the wearisome racking of the pick machine. The advantages of the pick machine, which is driven by compressed air, and strikes about 190 to 210 blows per minute, are, first, that it can be used in mines where the narrow conditions of room and floor do not permit the introduction of chain breast machines; and, second, that in mines where the quantity of gas is so great that safety lamps have to be employed it obviates the dangers which might arise from sparking if a motor-driven machine were employed.

As already noted, several long-wall machines—driven sometimes by compressed air, but frequently by electric motors—are in use. As the name indicates, in long-wall mining the coal is extracted from a long face, which is gradually moved forward in widening, irregular circles. The nature of long-wall work is such that the face must be jagged or circular instead of straight and regular, as in room-and-pillar mining. One of the leading types of long-wall machines, involving to a certain extent the principle of the chain breast machine, consists of an endless chain operated along a narrow frame or arm extending from the side of the machine and so adjusted that it can be operated at any angle up to a right angle. A change in the angle of the cutting frame will increase or diminish the thrust on the track; in the same way the machine can be made to follow any irregularity of the face of the coal. The cutting frame can be extended over the right or left side, so that as the machine moves the cutting can be accomplished in both directions along the coal face. The height of the machine is only 18 inches, and its weight is only about 3,000 pounds, so that it can be operated in very thin veins. It has a wide range of cutting speed, and can be made to undercut to any practical depth. In going through narrow places and also in moving or changing the cutting bits, the cutting frame can be swung out behind the machine instead of from the side. Like the ordinary chain machine it is operated by two men, and is said to be as available for room-and-pillar work as for long-wall mining.

Shearing machines constitute another class of apparatus of this nature. They are built on the general plan of the chain undercutting machine. The cutter frame is located in a position normal to that of the undercutting, the shaft in the armature of the motor being parallel to the center rail. The best way of shearing a room or entry with such machinery is to make the first cut at the top of the vein, and then let the machine down far enough to make another cut. To provide for the secure and rigid support of the machinery the frame is clamped tightly to two columns, at points in line with the balancing position, and the front end is steadied by two auxiliary columns; the four columns vary in length according to the thickness of the vein worked. The capacity of the machine for cutting depends upon local conditions. With a standard type of this machine a single cut is 36 inches high, about 4 inches wide, and from 5 to 7 feet deep. From 50 to 100 feet of entry can be cut in a day of ten hours. Current for moving the machinery from one working

PLATE II.—ELECTRIC COAL CUTTER.

PLATE III.—ELECTRIC COAL CUTTER.

place to another can be taken from trolley wires, and the machine can be run up to the face of the entry, which can be sheared without removing the machine from its truck wheels.

Drills.—The application of electric drills to mining work has been the subject of considerable study and experimentation for many years past, but not until recently have these drills been successful. Drilling is one of the few classes of operation in which a reciprocating motion is preferable if not necessary. The air drill has a reciprocating motion; the electric drill, on the other hand, necessarily has a rotary motion, the effort to develop electric power practically by reciprocating motion having been abandoned at a very early stage in the development of the electric motor. Moreover, the air drill has shown itself very hardy and capable of withstanding unlimited rough usage; whereas the electric drill has usually proved to be a delicate and sensitive piece of mechanism, easily deranged and expensive to repair. On the other hand, the degree of efficiency of the air drill is relatively low, the electric motor being able apparently to do the same work with a consumption of about one-tenth of the power. Moreover, the electric drill does not sustain the further loss in efficiency to which an air compressing plant is subject at a high altitude, nor is it affected by a low temperature, which in an air compressing plant freezes up the exhaust.

A report has recently been made in some detail with regard to results obtained with electric rotary drills as compared with air drills in some potash mines in central Europe. For the electrical equipment current is distributed through the mine by armored cables fastened to the roof. The motor is furnished with a reversing arrangement, such that two wires of the cable can be interchanged; by this means the rotating field of the motor, and therefore the direction of rotation of the motor, is reversed. The motor has a starting resistance; it develops normally about 1 horsepower, but can be overloaded with 1.5 horsepower for a certain length of time. The connection between drill and motor is made by a flexible shaft. The weight of the drill proper, which is fastened between two screw columns, is 99 pounds. The feed has been varied from 4 to 20 inches in one minute.

From a comparison of the weights and initial costs of electric and of air drill outfits presented in the report referred to it appears that the former is considerably heavier and more expensive. The annual cost of maintenance, however, amounts to from $16.63 to $19 for the electric drill, and to $29.69 for the air drill. Moreover, in spite of its greater weight, the electric drill can be erected and dismounted just as quickly as the air drill, principally because of the easier adjustment of the screw columns. To support the air drill these have to be screwed up with considerable force and strengthened, while for the electric drill, which works quietly and without jarring, they do not have to be fixed so rigidly. The adjustment of the electric drill itself is easier than that of the air drill, and when the screw column is moved the electric drill is left fastened to it. Tables of practical tests are given, recording the depth of hole, net time of drilling, drill pauses, total time of drilling, total and net time for 1 meter, and the number of replaced drills. From these tables it appears that the electric system affords a considerable saving of power and time. The efficiency of both kinds of apparatus is calculated in detail from the generating station to the drill; it is stated that the total efficiency of the electric drill is 0.29, while that of the air drill is 0.0223, or about as 1 to 13.

In coal mining operations the use of electric rotary drills and augers is quite common, and appears to be thoroughly successful from the fact that the rotary motion of the motor armature can be fully availed of. These drills are used for boring holes into the coal for shooting it down after it has been undercut. Many admirable types of these drills are illustrated in the catalogues of the manufacturers and are in wide use. They are so arranged that they can be operated at almost any angle, vertically or horizontally. They are generally mounted on light upright stands, with screws at the ends for fastening to the roof and floor, but some of the larger drills are mounted on trucks, so that they can be transported readily from place to place. The motors, which often are very small and light, not much heavier than a good sized fan motor, are mounted with an adjustable clamp, and are geared for either single reduction or double reduction, for reducing the high speed of the armature to that which is suitable for the auger. The larger rotary drills of this class have been equipped with motors of from 4 to 6 horsepower, the power being transmitted from the motor to the drill by means of a telescopic shaft and machine-cut bevel gears. The telescopic shaft consists of a steel tube in which slide two solid shafts, each of which is fitted with a universal joint, and is fastened to the motor and to the drill machine by means of an automatic coupling.

A number of electric percussion drills, striking a percussive or hammer blow, are in use. They are of various sizes. In some of them the power is transmitted from the motor to the drill by a flexible shaft, which may be several feet in length. In one form, equipped with a self-contained motor, the hammer proper is operated by a pair of eccentrics on a shaft connected through simple gearing to the armature of the motor. The raising of the hammer is effected during a three-quarter revolution of the eccentric shaft, and the blow is struck during the remaining quarter. A very powerful hammer blow is thus secured, at the rate of about 400 to 500 blows per minute.

Shot firing.—The electric method of shot firing in mines has reached considerable development of late years, and is now in general use. As a result of its investigations, the British departmental committee,

already referred to, decided in favor of requiring electric shot firing in all pits to which the orders as to explosives in coal mines apply, and it is understood that in the majority of such pits this method has already been adopted. The order regulating the use of permitted explosives lays down the rule that the firing must be done with an efficient electrical apparatus, or by other means equally secured against the ignition of inflammable gas or coal dust.

There are two methods of electric blasting or shot firing—known as the high-tension and the low-tension—in ordinary use at the present time. In the high-tension method the explosion is caused by a spark which is made to jump between two points inside the detonator. The current for this spark is created by what is known as a magneto machine—an armature revolving rapidly in front of a set of permanent magnets, the whole mechanism being inclosed in a small box from which the handle attached to the armature extends. This box is portable and can be set down anywhere, and the wires from it can be carried a considerable distance. In the low-tension method there are employed similar magnetos of low tension, or chemical batteries. In this method the two wires which extend into the charge are connected, or bridged, at their ends within the priming with a short piece of fine platinum or similar wire. This wire offers considerable resistance to the passage of even a small current, so that it rapidly becomes heated to incandescence and thus ignites the priming, which in turn explodes the detonator charge.

The high-tension system is in very common use and can be seen in operation in almost any city where building foundations are being excavated in hard material. The low-tension system is quite popular in mines, however, the principal reason being, apparently, that the fuses are less subject to deterioration and can be stored more safely than high-tension fuses. They differ from the high-tension, spark-jump fuse also in that they can be tested by means of a battery and galvanometer in order to see if they are alive. The shots are fired either in series or in parallel; if the former, the current needs considerably higher tension in order to pass successfully through all the charges, but if in parallel a much lower tension is available, so that a battery of cells can be used.

The British departmental committee already mentioned pointed out two dangers to be apprehended from electric firing: First, the ignition of fire damp from a spark in the magneto machine or between the bare wires when in close proximity; and, second, the premature firing of the shot. To guard against the first danger, high-tension magnetos are inclosed—as has already been stated—in a flame-tight case and the fuses or detonating wires are connected up in such a way that there is no possibility of a spark passing from one wire to the other. Premature firing would appear to be the principal cause of almost all accidents, but in most instances carelessness is a contributory cause. It is difficult to see how the shot can be fired prematurely if the firing cable is first connected to the fuse wires and not attached to the firing apparatus until the shot firer is ready.

The British committee recommends that as an additional precaution the responsibilities be limited and the degree of safety increased by providing all magneto machines and cell batteries with removable handles, keys, or safety plugs, which should always remain in the custody of the shot firer. With regard to the use of batteries, it is urged that unless deterioration is carefully looked after they are of doubtful advantage for shot firing, because while their original cost is but a fraction of that of the magneto the cost of maintenance and of efficient working is much greater.

Mining traction.—The electric locomotive is one of the most striking examples of the application of electricity to mining, and its general use may be inferred from the report of the bureau of mines of Pennsylvania for 1902, which stated that there were 378 electric mining locomotives in use in the bituminous and anthracite regions of that state. Another fact bearing upon this subject is the statement in the Illinois coal report for 1901 that in 12 mines in that state over 2,000,000 tons of coal had been hauled by electricity during that year. These figures deal with haulage within mines, but it should be remembered that in many of the mining regions trolley roads are in use for handling ore, etc., which would correspond to freight roads, and for which no particular type of locomotive is necessary. It is believed that of locomotives built especially for such work about 3,000 are now in use in mines in the United States.

The first specifically electric mine locomotive employed in the United States was built nearly twenty years ago by Mr. W. M. Schlessinger for the Lykens Valley colliery of the Pennsylvania Railroad, and at last reports this machine was still in service. It weighed about 5 tons and was equipped with 32-horsepower electric motors, from which motion was imparted to the driving wheels by a chain and cog or sprocket connection. The conductor for supplying current to the locomotive consisted of a light T-rail carried on supports parallel to the track at a vertical height of about 5 feet and removed horizontally from the track rail about 20 inches. Current was conducted from this rail by means of three wheels pressed against it by a trolley arm, and the track rails were used as the return circuit. The ordinary train for this locomotive, which operated with a current of 450 volts and from 40 to 200 amperes, was 15 cars, each of which weighed 1 ton when empty and carried 2.35 tons of coal or 3 tons of rock. There were two haulage lines, one 9,500 feet long, in a drift, and one 10,400 feet long, in a tunnel.

Another early electric mine locomotive still in use is of 40-horsepower capacity and uses current at a pres-

PLATE IV.—ELECTRIC DRILL AT WORK IN A MINE.

sure of 220 volts, with a wheel gauge of only 36 inches. This machine is 5 feet 6 inches in height and weighs 10,500 pounds, with 1,800 pounds added to increase traction.

Some of the earliest work was done in Ohio, and after fifteen years of continuous service two of the first electric locomotives ever seen in a bituminous coal mine are still in use, hauling the output of a mine operated by the Upson Coal Mining Company, of Shawnee. It is interesting to note that this type of locomotive approximated street car practice, having a single motor with a double-reduction gear.

These locomotives, however, are examples of earlier practice in mounting the motors above the truck and gearing downward, thus requiring greater height than is now usual. Transition was soon made, however, to types of "terrapin-back" or "turtle-back" locomotives, bringing the motor much nearer to the ground, so that it could be coupled with the axles by means of connecting rods. In later types each axle of the locomotive has been connected with a separate and independent truck-mounted motor.

Modern mining locomotives range in size—according to the work they are designed to perform—anywhere from 2 to 20 tons, and their wheel gauges range from 18 inches to the standard railway gauge of 4 feet 8½ inches. The traction locomotive consists, broadly, of two iron frames within which are contained the motor and driving mechanism, the controller wheel being usually placed in front, vertically, within convenient reach of the motorman, who is seated; in some locomotives, however, the controller and hand wheel are placed on top of the locomotive, in a horizontal position. The motors are usually geared to the truck axles by means of cut steel gear wheels, and the traction wheels are shrunk and keyed upon the truck axles, being placed either inside or outside the locomotive frame. Electric headlights and mechanical brakes are used. The current is taken from an overhead copper trolley wire by a grooved brass trolley wheel, mounted on a short, stout trolley pole, and conveyed through the controller to the motors and back to the generators by means of the track rails, which are copper bonded, in order to insure a return circuit of thorough conductivity. A speed of from 6 to 10 miles per hour is usually made.

Because of the limited dimensions of ordinary mine entries and the light weight of rails, the 20-ton mining locomotive is about the largest that can be used to advantage. Greater hauling capacity is sometimes needed, however, and accordingly a double locomotive has been introduced, consisting of two standard 13-ton mining locomotives, one of which is provided with a 4-motor controller and a 4-motor commutating switch, so that the complete machine is operated from the one controller. Here again, mining practice harmonizes with that obtaining in electric railway work in the adoption of what is known as the "multiple-unit control," by means of which the control of motors over a whole train of vehicles can be brought to one point and there manipulated by one motorman, instead of being distributed, with each set under the control of a separate driver.

In an interesting paper, read before the Western Pennsylvania Central Mining Institute, in December, 1903, Mr. W. L. Affelder, superintendent of the Mosgrove coal works, in Pennsylvania, stated that a 10-ton 30-inch gauge "gondola" locomotive which had been in operation there for more than a year had never been idle a day on account of defect or accident. During that time it had hauled nearly 150,000 tons of coal, at a cost of less than one-tenth of a cent per ton for repairs. As many as 35 loaded cars, each weighing 3,700 pounds, are hauled by it up a grade of 3 per cent, 250 feet long. At a point in the mine where the grade is 4.5 per cent in favor of the load for 125 feet, and then 3 per cent for an equal distance, the locomotive holds back as many as 35 loaded cars with every car wheel running free.

Figures taken from various mines in the coal fields, and compiled by Mr. F. J. Platt, show a generally high degree of efficiency in electric haulage. At the Green Ridge colliery, Scranton, Pa., the cost of haulage by mule power was estimated at 7.15 cents per ton and the cost of electric haulage at 2.76 cents, showing a saving by electric haulage of 4.39 cents. At the Sturges shaft of the New York and Scranton Coal Company the cost for haulage by mule power was estimated at 6.58 cents per ton and the cost of electric haulage at 2.62 cents, showing a saving by electric haulage of 3.96 cents.

A special feature of electric haulage in mines is the use of "gathering" locomotives. In most coal mines the cars are gathered or collected from the working faces of the rooms by mules or horses, though in some low-veined mines where it is necessary to use very small cars they are pushed between the working faces and the "room necks" by the miners themselves. They are then collected by locomotives and hauled in trains to the tipple or shaft bottom. In many cases it has been difficult to enlarge the entries sufficiently to accommodate the mule, because of the cost of "brushing" the roof or "taking up the bottom," especially where a hard slate or rough limestone has to be dealt with. One means of obviating this difficulty has been found in the use of compressed air locomotives, but electricity has been found particularly suitable for this class of work. Locomotives used for this purpose are equipped with a reel which carries a flexible insulated cable. One end of this cable is connected to the trolley line, and the current is conveyed to the controller on the locomotive through a contact at the reel. The reel is geared up with the axles or truck of the locomotive, so that the cable can be paid out or coiled up. The gathering locomotive system can be pushed to a considerable distance

from the end of the regular trolley circuit. An illustration of this class of work is to be found in the mines of the Jones and Laughlin Steel Company, at California, Pa. These mines have five 4-ton gathering locomotives. A train of empty cars is taken from the gathering junction and distributed by the motorman into the various rooms in his particular section of the mine, and on the return trip the loaded cars are gathered up. When passing through the entry the locomotive receives its current by means of a regular trolley pole, but when entering the room neck the pole is fastened down and the insulated flexible cable is hooked onto the end of the trolley wire, the rail still serving as the return circuit. It is stated that a crew of two men on such a locomotive can gather up from 100 to 120 cars, or from 300 to 350 tons of coal, in an eight-hour shift. One well-known mine has equipped its gathering locomotives with a separate truck or tender for carrying and operating automatically the cable reel; this, however, is not the preferred practice.

In the case above referred to mining locomotives are spoken of as operating with overhead trolley connections. There are instances, however, in which the third-rail method has been applied to such work. This type of rail is used not only for the conveyance of the current, but always also as a tooth rail, with which a geared wheel on the locomotive can engage frictionally. According to Mr. Affelder, in his paper already referred to, 90 electric locomotives of this sprocket or cog rail type are now in use in coal mines. As a means of climbing grades the electric locomotive possesses advantages which have caused it to be adopted in various parts of the world, subject only to questions as to the advisability of using the cogged third rail also as a conductor for the current. The first of the third and traction rail locomotives of the sprocket type appears to have been installed in this country in 1899 in the Star City (Indiana) mine of the Harder and Hafer Company, of Chicago.

In metalliferous mines, as distinguished from coal mines, the locomotive is usually smaller. An instance of such work is to be found in the haulage system of the United Gold Mines Company, of Victor, Colo.—the Cripple Creek district—where one 8-ton locomotive with a drawbar pull of about 3,500 pounds and a speed of from 8 to 10 miles per hour is used. This locomotive is equipped with a single high speed motor, placed in the center and on top of the frame, the motor shaft being connected to the drivers by gears. Current for this locomotive is generated at a waterpower plant 12 miles distant by a 3-phase alternating-current dynamo, transmitted at a pressure of 13,000 volts, stepped down and rectified at a substation, and delivered to the trolley at 550 volts direct current.

It is, therefore, not to be understood that electric locomotives find their only employment in coal mines. An interesting illustration of the extensive application of the electric mine locomotive is to be found also in the Quincy copper mine, at Hancock, Mich. The Quincy company has installed 15 electric locomotives, one of which is on the 4,400-foot level, current being supplied from the surface through substation transformer plants located underground. Another instance which might be quoted is the 8-ton mine locomotive at the Highland Boy Gold Mining Company's mine, at Murray, Utah, employed for hauling slag cars, and using double overhead trolley, so as to dispense entirely with the track as a return circuit.

Thus far the subject of mine traction has been considered from the point of locomotives supplied by overhead or underrunning trolleys, or by third rail, with current from a distant source of supply. It is possible, however, to employ self-propelling or automobile locomotives, equipped with storage batteries, so as to dispense entirely with the dangers and inconvenience of tracks and wires charged with exposed live current. The weight of the battery and the space that it necessarily occupies, however, increase the size and weight of the locomotives, and thus place a restriction upon this method of traction in many mining operations. Their use is therefore more particularly to be noted in connection with exterior work, and locomotives used for such work have considerable haulage capacity.

Several types of this locomotive are in use, either as simple automobile locomotives or as a combination vehicle employing the trolley over sections of the track where such use is permissible and safe. One well-known American manufacturer builds a locomotive of this type in which the batteries are carried upon a separate truck or tender, thus reducing the height of the locomotive to a minimum. This locomotive can be used for "gathering" purposes in low-veined coal mines, but its hauling capacity is necessarily limited, and by some authorities it is not considered feasible. In another type the batteries are mounted on the locomotive and are so arranged that the cells can be charged while the motors are being driven by current directly from the trolley wire. A smaller size of automobile locomotive is especially adapted to run on curves with a radius of 12 feet and a 21½-inch gauge. The current is estimated to cost about 50 cents per day of ten hours for a locomotive weighing from 4 to 6 tons and up to $1.50 per day for a 16-ton standard gauge locomotive. As a rule, the batteries are not worked quite so hard as those for regular automobile purposes, the requirements per pound of lead, instead of about 7 watts, being not more than 2 or 3. The advantages claimed for the battery, as compared with the trolley system, are that it can be run over any improvised track of appropriate gauge regardless of wire connections; that the first cost of the battery is usually less than the outlay on trolley wires and supports, including erection; and that the expenses of maintenance with good batteries also average lower.

A further modification of traction or haulage methods is found in the movable automatic loader used by the Illinois Steel Company. It is difficult to classify this apparatus, but it serves to move ore, and therefore belongs possibly as much in the transportation as in the loading group. The machine consists of an endless chain of metal arms or scoops mounted on a stout metal table or base, which in turn is mounted pivotally on a truck, to enable it to adjust itself to the pitch of the ground and to the height to which the material is to be elevated in loading—as, for example, to a line of the trolley mine cars. The chain of scoops, which is driven by an electric motor, passes around sprockets arranged at the opposite ends of the machine. The motor, which takes current through a cable reel from an adjacent trolley or other circuit, also propels the loader, moving it to any desired point by means of chain sprockets and suitable clutches. In operation the front edge of the table of the machine is lowered until it rests upon the ground, and it is then thrust forward against the pile of material. As the arms sweep around each arm or scoop gathers up a certain quantity of material and carries it into channels on the table until it reaches the upper end of the machine, when it is emptied into the desired receptacle. The arms travel at the rate of about 60 to 80 feet per minute, and the capacity of the machine is reported as 90 cubic feet of loose material per minute. This machine is said to have been tested successfully in the handling of limestone, coal, and salt, and to have shown a considerable saving of time and money over hand labor with a shovel.

Telpherage.—An interesting and novel application of electric traction methods is to be found in the modern telpherage system. Up to the present time haulage of ores and other raw material in connection with mining work has often been conducted aerially, by means of a traveling wire rope or cable; and this use of the wire rope represents, in the aggregate, an enormous amount of work. As generally understood, a short stretch of such work, often with a span of several hundred feet between the supports, or between the support and the anchorage, constitutes a "cableway;" in this manner a river or a wide valley is bridged. A "tramway" cable, on the other hand, has frequent supports, and may be several miles in length. Electric telpherage belongs generically in the latter class, as it is not suited to very steep grades.

The fundamental difference between electric telpherage and the traveling rope system is that in the former case all the ropes or cables are stationary, the haulage being effected by means of an electric motor or "telpher" traveling along one of the cables, and taking its current, by means of a short trolley pole, from a trolley wire above. In the simpler form the telpher travels along a flexible wire cable; for heavier work a rigid metal rail supported between posts is employed, and upon this loads up to 20,000 pounds in weight can be moved at a speed of from 800 to 1,500 feet per minute.

This telpherage method was first experimented with several years ago in England and America, but only within the last year or two has it been practically introduced in this country and abroad. Its present feasibility is due to improvements in motors which can stand exposure, in methods of control, in contact devices, in brackets, etc. In an electric telpher system employed in a limestone quarry in the island of Cuba, the telpher with its cars travels upon cables, except at eight curves, where solid rail is employed. The buckets, loaded with limestone and carried below the telpher, take along the cable a maximum load of 1,200 pounds, with a speed of from 12 to 15 miles per hour. Current is derived from a distant power plant, and to start the telpher all that is necessary is to close the switches at the ends of the system. This telpher travels automatically, but in the case of larger apparatus a cab is provided for a telpher man, as on an electric crane, so that he can travel with the load of coal, sulphur, phosphates, etc., and assist in loading and unloading.

Even where regular wire rope haulage, in the shape of cableways, tramways, and surface lines with rails is employed, it has been found feasible to replace with an electric motor the driving engine operating the drums of cable. A number of plants with electric cable haulage have been installed in South Africa, Japan, Europe, and other parts of the world, the hauling motor and cable drums being placed usually at the top of the incline, so as to raise the loaded cars. The speed in such work is usually from 4 to 6 feet per second on a grade of from 10 to 15 degrees.

Hoisting.—Electric hoisting is a growing feature of the use of electricity in mines, and a large amount of work has already been done in this field with the object of replacing the steam engine with the electric motor driven from a central plant. To quote a paper read by Mr. F. O. Blackwell before the American Institute of Mining Engineers, at Albany, in February, 1903, "The throttling of steam to control speed, the necessity for reversing the engine, the variation in steam pressure, the absence of condensing apparatus, the cooling and large clearance of cylinders, and the condensation and leakage of steam in pipes when doing no work are all against the steam hoisting engine. One of the largest hoisting engines in the world was recently tested and found to take 60 pounds of steam per indicated horsepower per hour. The electric motor, on the other hand, is ideal for intermittent work. It wastes absolutely no energy when at rest, there being no leakage or condensation. Its efficiency is high, from one-quarter load to twice full load." As a matter of fact this class of work touches closely that above referred to in connection with inclined traction haulage, for after all an elevator is virtually a railway with 100 per cent grade. With these equipments great care is

taken to regulate and control the apparatus for safety purposes with safety and emergency brakes, etc.

One of the instances cited by Mr. Blackwell in his paper is that of a flat rope double-reel hoist operating in the Free Silver mine, at Aspen, Colo. In this case the hoist works in a vertical single-compartment shaft, with guides for extra weight, and is driven by a direct-current motor of 120 horsepower at 650 revolutions per minute, with different gears to give 20 and 32 revolutions to the drum. The speed of hoisting ore is from 315 to 630 feet per minute, and that of bailing water from 510 to 1,020 feet per minute.

In one gold mine where steampower has been superseded by an alternating current induction motor, the hoist moves through the shaft at the rate of 1,250 feet per minute, double deck cages carrying 3,600 pounds of ore, thus elevating 500 tons daily from a 2,500-foot level. It is stated that this system has shown a net efficiency of 75 per cent, taking into account all electrical and frictional losses, and that the average cost per horsepower per month has been reduced from not less than $20 to $7.

Another illustration of an electric motor mine hoist is furnished by the plant installed in one of the pits of the Gelsenkirchener Bergwerks-Aktiengesellschaft, in Germany. This equipment is designed to raise in one lift, when working at its maximum capacity, a load of 4 tons of coal at a speed of 65 feet per second. The daily hoisting capacity in sixteen effective hoisting hours would be 2,700 tons with a single unloading platform, 3,200 tons with two platforms, and 4,000 tons with three platforms from a depth of 1,641 feet. The two cages are attached to an endless rope which at the top passes half around and fits into an oak-lined sheath on the circumference of a drum 20 feet in diameter. On each side of the winding is a direct current motor, the current supply of which includes a storage battery.

Another interesting hoisting equipment is that installed in the Fortschrittschacht-Brüx mine, Bohemia, where the hoisting engine is driven by a direct current motor of 80 horsepower, with two winding drums, which hoist from a depth of 969 feet at a speed of 787 feet per minute with a single layer of steel rope, the gross load being not quite 4 tons.

Still another instance is the hoisting engine driven by an alternating current induction motor of 120 horsepower, installed in the Germania colliery, in Westphalia, Germany. The winding drums are each 3 feet 8½ inches in diameter, revolving through double reduction gearing at the rate of 16 revolutions per minute. The motor, which develops 200 horsepower at the beginning of the hoist, winds a normal load of 1¾ tons from a depth of 1,500 feet at a speed of nearly 10 feet per second; the load can be increased to 3½ tons, however, with a corresponding decrease in speed.

A large hoist, with winding drums 19 feet 8 inches in diameter, erected for the Harpener Mining Company, at Dortmund, Germany, lifts 100 tons of coal per hour from a depth of 2,300 feet at a speed of 52½ feet per second.

Another interesting illustration is the plant recently constructed for the famous Comstock mine, at Virginia City, Nev. The power plant is situated on the Truckee river, 32 miles from the mine, and the present substation is located at Virginia City. Electric hoists are used extensively, the largest being of the balanced tail-rope system, driven by a 200-horsepower variable-speed alternating current induction motor.

Pumping.—Electric motors have been found extremely useful and successful in a large number of cases for driving the pumps which are employed to remove the accumulations of water in mines. It is said that the efficiency even of small reciprocating pumps is not far from 80 per cent, and that large pumps give as high as 90 per cent.

One of the problems encountered in connection with this application of electricity has been the proper regulation of the speed of the motors for the purpose of varying the amount of water pumped. In direct current motors this is done by varying the field strength; the electric pumps which have been in operation for ten years past in the Calumet and Hecla copper mines, in Michigan, have adjustments of speed of 2 to 1 under this system. When induction motors are used the windings are thrown into different combinations for various numbers of poles and rates of speed, and several frequencies, also, are provided for. Some alternating current motors employed in electric pumping operations are of noteworthy size, developing as much as 650 to 750 horsepower.

For electric pumping the pump itself need embody no special features. Both reciprocating and rotary pumps are used; they may be either horizontal or vertical, and reciprocating pumps may be of either piston or plunger type, according to the circumstances of the installation. Where a reciprocating engine is employed, however, it is generally considered advisable to use a double acting pump, either duplex or triplex. A triplex double acting pump does not require so large a motor as does a simplex acting pump doing the same duty. To raise a great quantity of water against a certain head takes just so much power, but if the work be divided among two or three acting cylinders there will necessarily be a more uniform flow of water, and hence the strain on the motor and the pump will be reduced.

No fewer than 50 electrically driven pumps of the reciprocating class are in operation in the mines around Johannesburg, South Africa, some of them delivering as much as 200 gallons per minute working against a 500-foot head. A striking illustration of electric pumping work is furnished by the Arniston colliery, near Edinburgh, Scotland. One set of pumps of the 3-throw type, with 11-inch rams and 18-inch stroke,

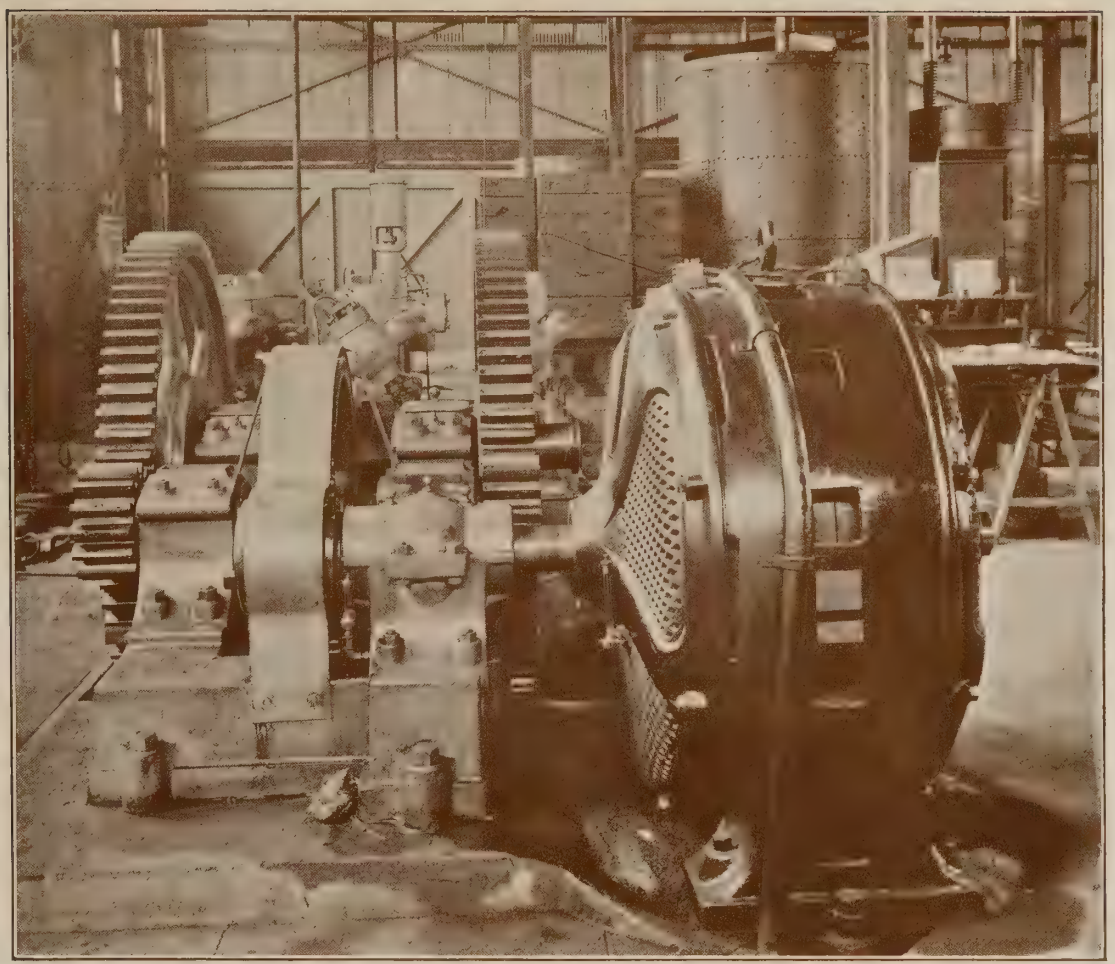

PLATE IX.—MINE PUMP, DRIVEN BY A 150-HORSEPOWER MOTOR.

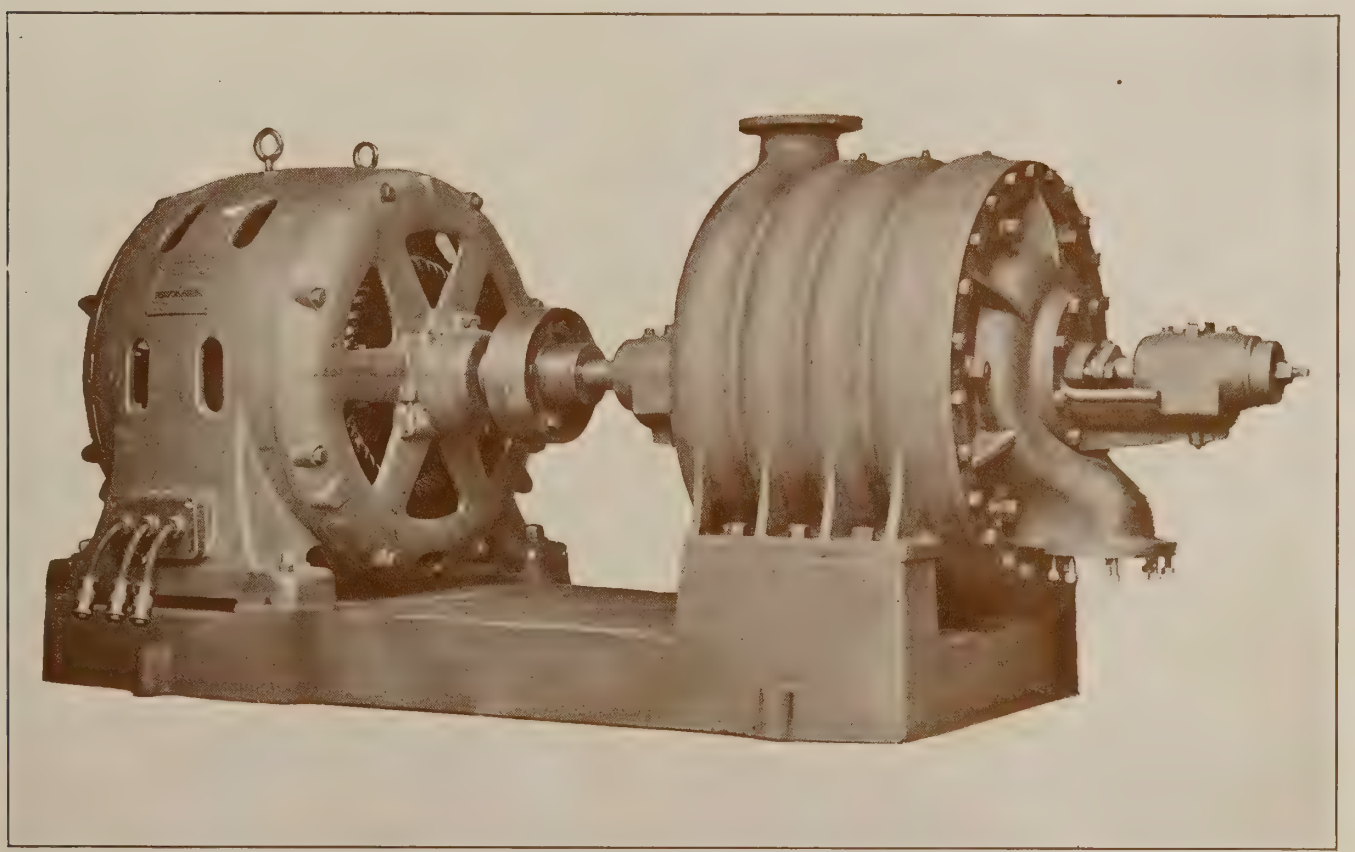

PLATE X.—FOUR-STAGE MINE PUMP, DRIVEN BY A 150-HORSEPOWER MOTOR.

delivers 500 gallons per minute against a head of 678 feet. Each of these pumps is driven by an 80-horsepower motor and runs with a speed of about 30 revolutions per minute. Another set of pumps, similar to the above, delivers 500 gallons per minute against a head of 256 feet through 3,175 feet of cast iron pipe. These pumps are of the same diameter and stroke as the others, and are equipped with 80-horsepower motors. Three sets of pumps have also been installed to the dip, each set capable of delivering 100 gallons per minute against a head of 450 feet. These pumps deliver through 1,200 feet of 6-inch pipe, 9-inch stroke, and are equipped with 25-horsepower motors.

On the continent of Europe what are known as express pumps have been largely installed, the name being applied generally to any reciprocating pump run at high piston speed, although applied also to a special system of large, high-speed pumps with mechanically closed suction valves. An example of an electrically driven express pump in mining is one in Bohemia, which runs at the comparatively high speed of 200 revolutions per minute and is capable of lifting 132 gallons per minute against a head of 1,312 feet.

On account of its rotary motion and its high speed, approximating the speed of a motor, the centrifugal pump also is peculiarly suited for electrical operation, the pump and motor being usually direct connected. This pump has been found of special utility in working against low heads and for handling muddy water.

The use of rotary pumps coupled direct to small motors running at high speed in place of reciprocating ram or plunger pumps has met with approval in Europe. These rotary pumps are made with several chambers placed in tandem and are of a type between an ordinary centrifugal pump and a form of reverse turbine. One built in Germany has 4 chambers and 4 impellers and is coupled direct to an alternating current motor of about 85 horsepower, which, when run at 1,335 revolutions per minute, has lifted 440 gallons of water per minute to a height of 394 feet. By increasing the number of impellers to 6, this pump can be made to reach 1,150 feet in one lift. An efficiency of between 70 and 75 per cent is claimed for this type of pump.

Another type of electric pump is the sinking pump. The electric sinking pump can be lowered from one location to another in much less time than a steam or compressed air pump, and as it can be completely submerged it does not have to be relocated as often as a steam pump. The question of what would happen to an electric motor in a mine if pumps and motors get flooded has often come up. From tests made recently at the University of Liége, Belgium, it appears that a suitably designed polyphase alternating current motor will suffer very little damage. A 3-phase mining motor of a type largely used on the continent of Europe was completely submerged in water. It was run for a quarter of an hour; it was then stopped and allowed to remain submerged, under official seal, for twenty-four hours, at the end of which time it was again run for a few minutes. It was next removed from the water, again put under seal, and left to dry for twenty-four hours. The insulation was then tested, and the motor was found to be in perfect order. It would be hard to imagine a test more severe than this.

As bearing upon this question it is interesting to note that among the pumps in use around Johannesburg, South Africa, at the beginning of the Anglo-Boer War, there were twelve of a well-known American make, each of which was operated by a 50-horsepower induction motor of American construction with three 15-kilowatt transformers. When the mines were shut down, upon the breaking out of the war, the water rose so rapidly that it was impossible to remove the pumps, motors, transformers, etc., and consequently they remained under 500 to 1,000 feet of water. Two and a half years later, when peace was declared in South Africa, the water in the shaft was pumped out and the electrical apparatus was removed to the surface. Three of the motors were stripped and completely rewound, but to the general surprise of the experts the condition of the insulation indicated that the rewinding might not be absolutely necessary. Accordingly the other nine motors were thoroughly dried in an oven and then soaked in oil. After this treatment they were rigidly tested, proved to be all right, and were at once restored to regular service in the mine. The transformers were treated in the same manner as the motors, with equally gratifying results.

An interesting illustration of the flexibility and adaptability of electric motors for pumping purposes is furnished by the Gneisenau mine, near Dortmund, Germany, where a very large electric mining plant was installed in 1903. In this instance the pump is located more than 1,200 feet below the surface, and the difficulties of installing the apparatus were so great, on account of the small cross section of the shaft, that it was necessary to build up the motor in the pumping chamber, the material being transported through the wet shaft and the winding of the coils being performed *in situ*.

An interesting use of the electric pump associated with the telephone in connection with mining is noted by Mr. W. B. Clarke. In one coal mine, where an electric pump is located in a worked out portion of the mine, the circuits are so arranged that the pump is started from the power house, some distance away. Near the pump is placed a telephone transmitter connected to a receiver in the power house. To start the motors, or to ascertain whether the pumps are working properly, the engineer merely listens at the telephone receiver, without leaving his post.

Lighting.—From the earliest days of practical electric lighting, the availability of the method for mining was recognized; and electric illumination in some form

or other is now used very widely. Of the two forms—the arc and the incandescent—the latter is very naturally preferred underground, for various reasons. In the first place, the subterranean spaces to be illuminated are restricted in area, so that small lights are sufficient; in the second place, both the earlier arc lighting circuits and a great many of those in use to-day have involved the employment of dangerously high pressures; and in the third place, there is objection to employing underground an open-flame lamp, such as the ordinary arc lamp has always been. Hence, while a large number of mining plants utilize arc lamps, these are to be found above ground, while the lighting below the surface depends upon incandescents. The advantages claimed for incandescent electric lighting are: The flexibility of the system, making it possible to move circuits readily from one part of the mine to another, the absence of fumes and smoke, less danger of fire, decreased cost, generally better lighting, and reliability of the light under all the variations of temperature and barometric pressure.

It follows that the electric lighting in mines is usually of a composite type, the arc lamp being used at the surface, in buildings, yards, sidings, outworks, etc., while the incandescent lamp is used in the mains, levels, tunnels, etc. At one time, in order to accomplish this dual purpose, it was necessary to install two types of generating dynamos—one for the high-pressure arc lighting and the other for the low-pressure incandescent lighting; but the later developments and improvements in arc lights have made it possible to operate them on the same circuit as the incandescents and in conjunction with motors, and hence recent years have seen the installation of standard types of direct-current dynamos for all services, operating at voltages of 100, 220, 550 volts, etc.

The British departmental committee already cited laid down, with regard to the installation and use of electricity in mines, a few simple rules, aiming at continuity of service and the prevention of the escape of current. It is provided that for lighting purposes only low pressure shall be used, and that lamp holders, switches, or other fittings must not be fixed directly to the timber or metal work, but must be attached to hardwood or other incombustible, nonhygroscopic insulated base blocks. Small wires or derived circuits for lighting must be noninflammable or suspended from porcelain insulators, or fastened to them with some nonconducting material which will not cut the insulated covering and which will not permit the wires to touch any timber or metal work. Staples of all kinds are prohibited. If metallic pipes are used, they must be electrically continuous, and must be earthed or connected to ground. If separate uncased wires are used, they must be kept at least 2 inches apart, being brought together only at switches or fittings. Wire for lighting purposes underground is not to be of flexible cord; in other words, it is not to undergo the mechanical strain of supporting a lamp. It is especially required that in places where there is liability to fire damp, etc., incandescent lamps must be used, inclosed in gas-tight fittings of strong glass without any flexible cord connections, and with the wires protected by a strong exterior metallic sheathing, sufficiently grounded.

These general conditions are observed in all well-conducted mines, both in this country and in England, and special pains are taken with regard to the fittings, so as to protect the lamps from injury, and also to get as much light as possible from each lamp. Where the incandescent lamps are subject to vibration special types, with anchored filaments similar to those employed on trolley cars, are used.

One feature of electric lighting worthy of note, but not of great importance, is the use of portable miners' lamps. A great many efforts have been made in this direction with electricity, the lamps depending for their supply of current upon either primary or storage batteries. In either case, the drawbacks have been the weight, delicacy, high cost, and uncertainty of the apparatus, and the fact that such lamps are not usually of the safety type by which the presence of choke damp or other dangerous gases is revealed. In connection with these portable electric lamps for miners, small bulbs and filaments are used, so as to reduce the consumption of current to a minimum, thus making the batteries last longer.

Very few records of tests as to electric mine lighting are obtainable; in fact, very few such tests appear to have been made. The most important series is that made some six years ago in behalf of the Westphalian miners in the testing gallery of the consolidated collieries near Gelsenkirchen, dealing with the dangers that arise from the use of electrical appliances in gaseous mines. The results of the investigation, embodied in a report made public during the present year, may be summarized as follows:

Naked filaments raised to high incandescence may or may not cause explosions, and may remain intact and burn after explosion; in most cases ignition seems to follow the breakage or burning of the filament and the accompanying sparking. Lamps with their bulbs attached were purposely shattered, the bulbs and filaments breaking simultaneously and producing bad sparking, sometimes with and sometimes without an explosion. In other cases the filaments remained intact when the bulbs were smashed, and here again explosions sometimes followed and sometimes did not. Currents of not less than 9.6 amperes, continuous or alternating, did not produce ignition, but often produced sparking; stronger currents generally did give ignition.

Electric incandescent lamps are recommended, as affording probably the safest underground illumination. The conclusions as to lamps are: Use stout globes with round bulbs, to prevent cracking from the dripping of

water on the hot bulbs; and for further protection, inclose them in wire cages. Use low-current lamps (maximum of 9.6 amperes) and high voltage—but not above 150 volts, for all excessive voltages are dangerous. Have short leading-in wires for the lamps, far apart, to guard against their being bent together and thus making a short circuit; for the same reason avoid lamps with two filaments in series. This summing up is against the common portable lamp, which has the further disadvantage of not indicating the presence of fire damp.

But little was done in these tests with arc lamps. They appear not to ignite coal dust, even in an atmosphere of 4 per cent of marsh gas, and it is noteworthy that a dust storm did not make the arc flare up; but in 6 per cent of marsh gas explosions took place, whether the lamp was already burning or was switched in. Arc lamps, both continuous and alternating, must be condemned for fiery mines, although it should be noted that arc lamps have been used with impunity in rubber works, where the air is saturated with benzine vapor.

As regards switches for one or more lamps, it was found that current strength, and still more the voltage and self-induction in the current, play an important part; and while in general slow switching in is dangerous, on account of arcs forming, rapid motion of the switch is to be avoided in the case of circuits with high self-induction, continuous or alternating. In some cases the switch was thrown 30 times before ignition occurred. Carbon points may glow without causing an explosion so long as there is no arc. Spark extinguishers which form a momentary arc are to be condemned.

Hot wire resistances seem in themselves harmless, but danger threatens from contact. A set of resistances was placed horizontally, and one hot spiral touching another caused an immediate explosion. Glowing wires did not cause explosions, even when the explosive atmosphere was driven through them by means of a fan; and an iron wire buried in coal dust and heated by the current until it arcked strongly did not ignite the dust, either when it was quiet or when it was stirred into a cloud. Fusing wires protected by a shunt may be considered harmless; but ordinary safety fuses of lead and tin acted poorly.

Ventilation.—A considerable amount of work is done in mines to-day in the way of ventilation by electric motors, the driving of ventilating fans and blowers by electricity having been found to possess many advantages. In addition to the large amount of work done in tunnels, there is considerable work done in galleries in the way of operating the main fans or blowers for the general ventilation of mines. The larger fans of this class are belt-driven, on account of their very low rates of speed, but the smaller ones are also to be found direct connected to the motors.

As pointed out by Mr. Daniel Burns, in his treatise on electricity in British mining practice, in most mines where galleries are driven some distance from the main airway it becomes difficult to ventilate properly by the ordinary methods. The ventilation of such places is always an important matter, especially in coal mines, where a considerable quantity of gas is likely to be given off. It can best be accomplished by placing a small fan at the entrance to the heading or drift, and by this means forcing in the required amount of air. The fans employed for this purpose are sometimes driven by belt from the motor, but in many instances the motor is direct connected. It is found desirable to inclose both the motor and the switches as thoroughly as possible, in order to minimize the possibility of explosions which might result from the gaseous conditions under which such ventilating systems may work.

The work of ventilation in galleries may be illustrated by the case of a Westphalian mine with a 40-horsepower motor driving a Pelzer fan, and producing 50,000 cubic feet of air per minute with a water gauge of 3 inches. The motor, which is of the alternating type, is located about half a mile from the generator. Another instance is the case of the Glückauf mine, at Sondershausen, Germany, where a belted motor of 100 horsepower has been installed to furnish the general ventilation, although the blower is in the immediate vicinity of the steam plant. Still another instance is the 400-horsepower polyphase motor employed in the Germania mine for general ventilation.

Placer mining.—A considerable amount of placer mining work has been done by electricity of late, particularly in the Western states. The best way to afford an idea of work of this character is to cite some of the later examples.

The Gold Pan Mining Company, of Breckenridge, Colo., which has the largest placer mining plant in the state, if not in the United States, depends chiefly upon electricity for its operation. The current is generated at a plant some 5 miles from the deposits and is carried to a substation at the mine at a line pressure of 10,000 volts, 3-phase alternating. It is used principally for the driving of pumps and the illumination of the works. Large bowlders are moved by two electrically driven portable cranes of the boom type, which use alternating current from the line, without transformation, and each of which is equipped with a motor capable of developing 30 horsepower. A large 150-horsepower constant-speed motor is used to drive a centrifugal pump which assists in keeping the pit dry. A large machine shop, in which are made the large wrought steel water mains employed in the placer system, is supplied with power by a 50-horsepower constant-speed motor.

In California the earliest placer mining, represented in a later stage by hydraulic working, upon which legislation imposed severe restrictions, has been largely superseded by dredging, which appears to have developed into a very profitable enterprise where power can be obtained cheaply. In fact, it is stated that,

with cheap electric-power dredging, land in which the gold averages less than 10 cents to the cubic yard pays for treatment.

The gold bearing placer soil of California has a depth of from 10 to 50 feet, being a gravel deposit left in the old river channels. After one or two holes have been put down by drills, for test purposes, and an analysis of gold bearing soil made, the dredges are put to work should conditions warrant it. Two types of electric dredge are used to secure the gravel for treatment. In one method the gravel is lifted through centrifugal pumps, while in the other—the method more generally used—it is handled by an endless chain of buckets.

The method of operation is very interesting. A boat is built in the basin or excavation where the operations are to be carried on, the necessary equipment is put on board, and the hole is then filled with water to a depth of from 25 to 40 feet. Current is brought to the operating motors on the boat by means of overhead wires and cables, the cable being usually run out from 400 to 500 feet from the shore. As a general thing, the current used is high pressure, alternating 2 or 3 phase, and the transformers for receiving it and stepping it down for use, although sometimes put on the boat, are generally placed on the bank, on a pole, or in a small substation. The dredge digs its own channel ahead of it, depositing behind it the soil which has been worked over. It may thus be said to carry its own little pool with it as the work shifts from point to point. The gravel is elevated into a grizzly or similar device, where the rocks are washed out of the soil and delivered to the carrier, which deposits them on the dump behind the dredger. The fine soil is next washed through shakers and riffles, the gold being deposited on saving tables, to be taken up with quicksilver, while the worked-over soil is deposited at the stern of the boat with the other residue.

Some idea of the character of the work may be formed from the equipment of the chain-bucket dredge operated by the Butte Gold Dredging Company. This dredge, which has a draft of 5 feet and is about 36 by 90 feet on the water line, is fitted with two spuds, each 50 feet long; one, of wood, weighing about 10 tons, and the other, of steel, weighing about 17 tons. The swing permits of a cut about 90 feet in width. There are 85 buckets to the chain, each bucket having a capacity of 5 cubic feet. The dredge is operated at a normal speed of 22 buckets per minute, and ordinarily will handle from 50,000 to 75,000 cubic yards of raw material per month. The stacker at the stern of the boat is about 90 feet long and 2½ feet wide.

The largest dredge yet installed is that of the Ashburton Mining Company, near Folsom, Cal., with 7½-foot buckets. Some idea of the electric power equipment may be formed from the fact that the induction motors for this dredge include one of 150 horsepower for the digger or bucket line, one of 20 horsepower for the winch, one of 75 horsepower for the centrifugal pump, one of 20 horsepower for the stacker, and one of 10 horsepower for the deck pump.

The Central Gold Dredging Company, of Oroville, Cal., has a typical equipment of motors of somewhat smaller size and greater variety, including one of 50 horsepower for driving the buckets, one of 15 horsepower for the winches, one of 40 horsepower for the centrifugal pump which delivers the water for washing the soil under treatment, one of 15 horsepower for driving the stacker or conveying belt which disposes of stones, one of 15 horsepower for the operation of the shaking screens, one of 3 horsepower for the deck and bilge pump, and one of 30 horsepower for operating the sand pump, which is used occasionally, when the sand accumulates too quickly at the back of the boat to deliver it out of the rock pile through a long pipe. The cost of operation in the Oroville territory, including the cost of electric power, maintenance, labor, repairs, and superintendence, but not including any allowance for depreciation or for interest on the investment, is estimated at from 5½ to 6 cents per cubic yard. The cost of power is estimated at 1½ cents per kilowatt hour metered. This seems low, but is an actual price. Some of the dredges operate 80 per cent of the time, and their electric power capacity and current consumption are indicated by the fact that the cost of current per month ranges from $800 to $1,200.

Miscellaneous use of electricity.—In addition to the more important applications of electricity to mining, already described, numerous applications of a miscellaneous character might be mentioned. The flexibility of electric circuits and the general adaptability of electric power have led to a wide range of applications, some of which are still in the experimental stage, while many others have already proved successful.

An instance may be found in the substitution of electric motors for steampower for driving air compressors, where the latter are still used for the operation of small tools, coal cutters, drills, etc. By this means the compressor can be placed conveniently near the point of application of the air, so as to avoid long and complicated systems of piping, with consequent inefficiency and heavy loss, whether of steam or of air. Electrically driven compressors sometimes have belt connections, but in many instances the motor and compressor are more directly connected. An alternating-current induction motor having a capacity of as much as 200 horsepower has been connected to the air compressor by spur gearing. In one California mine the installation of an electric motor to take the place of steampower for driving a 100-horsepower air compressor is reported to have reduced the average cost of operation per month from $1,800 to $672.

A novel and interesting application of electricity to mining is furnished in the large sand wheel equipment at the Calumet and Hecla mine, driven by a 700-horse-

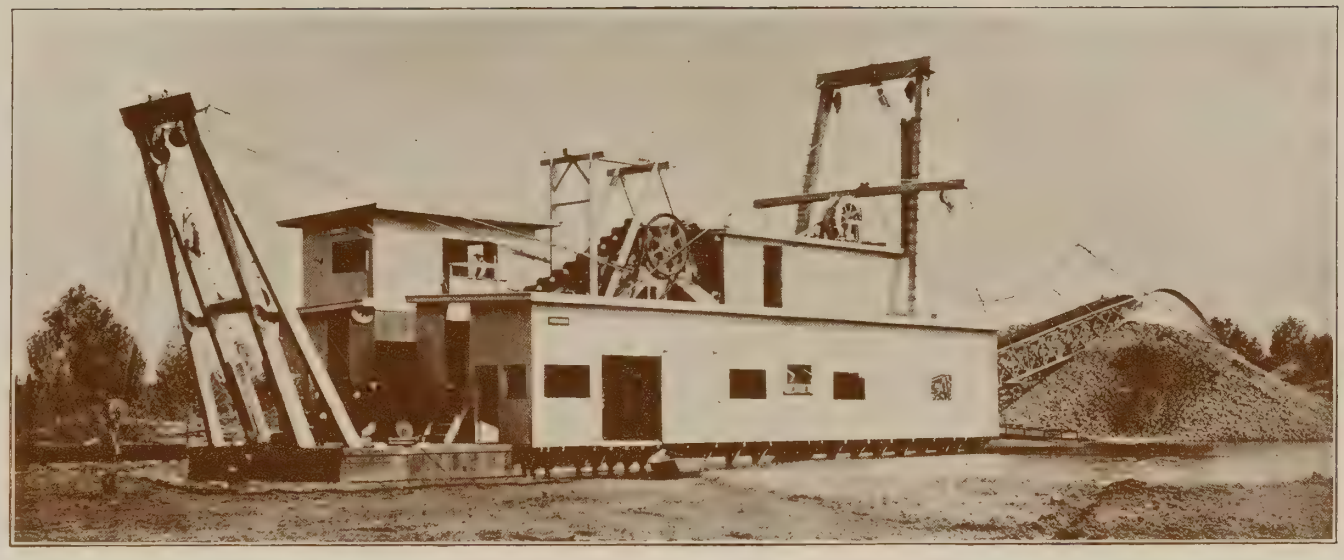

PLATE XI.—ELECTRIC GOLD DREDGER AT WORK IN CALIFORNIA.

power induction motor. To the rim of this wheel, which revolves in its pit at a speed of 10 revolutions per minute, are attached about 550 buckets for lifting the sand from the copper ore crushings. The electric sand wheel is considered to effect a considerable economy over the previous methods.

Signaling in mines requires a great variety of apparatus, such as telephones, telegraphs, bells, and appliances for sending signals according to the indications upon a dial. Of late years the telephone has gained ground rapidly over other methods of signaling. Several telephone manufacturers in the United States make types of telephones intended for mining work, with special regard to conditions of exposure, damp, etc. The British committee referred to previously records the fact that all of the witnesses before it, except one, spoke in favor of electric signaling in the shaft. Although admitting the fact that the difficulties in mines are greater than those in buildings, on account of the juxtaposition of heavy power cables and the presence of moisture, the committee recommends that as a means of ready communication between the power house and the motor equipments underground—a matter of great importance—telephones be put in all permanently installed motor rooms, so as to enable the men in charge underground to inform the engineer at once of any breakdown of motors, machinery, etc., and, if necessary, obtain assistance speedily. The committee notes the fact that for many years bare wires had been in use for transmitting signals without causing a single accident, and that, in fact, they had frequently prevented accidents.

In addition to the apparatus already described, a variety of appliances are employed for counting wagons, indicating the level of water, and kindred uses.

MINES AND QUARRIES BY STATES AND TERRITORIES

MINES AND QUARRIES BY STATES AND TERRITORIES.

INTRODUCTORY STATEMENT.

At the census of 1870, when the statistics of mining were first presented separately, they were summarized to show the totals in each state for each mineral and for all minerals. This practice was not followed at the censuses of 1880 and 1890, and comparable data are available for only a few states and the principal minerals. The great diversity of minerals now produced, and the great and increasing importance of the mineral industry in many states, make a summarization of this character again desirable. The detailed statistics for all productive mines in each state and territory, irrespective of the character of the ore, are shown in Table 2, and for the active but nonproductive mines, in Table 14, on page 57.

In the following discussion of the statistics for mines, quarries, and natural-gas and petroleum wells for each state, the states and territories are considered in alphabetical order. For each state a table is first presented, which shows the principal items for each of the leading minerals, and for all other minerals produced in commercial quantities during 1902. This table is followed by a general description of the state's mineral resources, and a summary of the statistics for the active but nonproductive mines. A brief résumé is also given of the products of manufactures that are closely allied to, or based on, the mining industry, because of the use of the products of mines as raw materials. The value of the production of the leading minerals is shown for a series of years, and the nature, occurrence, and history of each is discussed, together with a statement of the relative importance of the state in its production.

ALABAMA.

Table 1 is a summary of the statistics of the productive mines and quarries in the state of Alabama for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Iron ore.	Limestones and dolomites.	Sandstones and quartzites.	Clay.	All other minerals.[1]
Number of mines or quarries	260	145	59	33	7	5	11
Number of operators	172	91	31	29	7	5	9
Salaried officials, clerks, etc.:							
Number	947	623	227	63	6	.....	28
Salaries	$979,117	$709,449	$188,441	$54,597	$2,650	.....	$23,980
Wage-earners:							
Average number	19,132	12,930	4,864	1,002	58	33	245
Wages	$10,345,148	$7,841,457	$2,029,807	$354,718	$30,523	$9,634	$79,009
Contract work	$267,279	$265,579	$500	.....	.....	.....	$1,200
Miscellaneous expenses	$858,851	$734,972	$88,008	$25,954	$1,535	$3,866	$4,516
Cost of supplies and materials	$2,043,914	$1,219,310	$592,286	$149,012	$5,230	$1,993	$76,083
Value of product	$17,367,992	$12,419,666	$3,936,812	$759,617	$42,706	$19,742	$189,449

[1] Includes operators as follows: Bauxite, 1 (3 mines); cement, 1; gold, 4; graphite, 1; marble, 1; and pyrites, 1.

Alabama is especially rich in coal and iron, ranking fifth among the states in coal production and third in iron ore. It is also a producer of limestones and dolomites, sandstones and quartzites, clay, gold and silver, bauxite, graphite, marble, and pyrites. Extensive deposits of phosphate exist in what is locally known as the "black belt" extending across the central portion of the state. The phosphatic marls have very nearly the same percentage of phosphate and carbonate of lime as the Greensand marls of New Jersey.[1] In 1900 there was a production of 334 long tons of phosphate rock of a value of $544.[2]

Soapstone, as well as kaolin, is found throughout the metamorphic region of the state, large outcroppings that give very satisfactory results under fire tests occurring in Tallapoosa, Randolph, and Clay counties; these show indications of value for furnace linings.[3] The Indians made use of soapstone in many localities in the manufacture of various utensils. Not far from Tallahassee Falls there was the old Indian village, Tuckabatcha, near an outcropping of this mineral worked by them.

Tantalite has been found in the vicinity of Rockford, Coosa county, and a considerable amount has been sold for cabinet specimens. Tin found near Ashland, in Clay county, was mined at the Broad Arrow mines in 1883. The ore exists in considerable quantity, but is associated with titaniferous iron and can not be obtained in a sufficiently pure state to be marketable. Very pure specimens of tin ore were found, in 1880, near Rockford, in Coosa county, in association with tourmaline, biotite, and tantalite.[4]

Other minerals found in the state but not reported as commercially mined in 1902 are as follows: Beryl and feldspar, found in Coosa county; copper, in the old Woods or Copper Hill mine, in Cleburne county, which was worked awhile in the seventies, and is said to contain extensive ore bodies; and mica, formerly mined at Pinetucky, in Randolph county.

Development work was reported by 5 operators engaged in the development of gold and silver, bituminous coal, and iron ore deposits. They gave employment during the year to 10 salaried officials, clerks, etc., who received $9,010 in salaries, and to 45 wage-earners, who were paid $15,244 in wages. The miscellaneous expenses amounted to $889, and the cost of supplies and materials to $1,048.

Table 2 shows the value of the products of the manufacturing industries of the state, based primarily upon minerals mined and quarried, and the value of all products manufactured in Alabama in 1900.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$80,741,449
Based upon products of mines or quarries:		
Chemicals and allied products	$2,068,162	
Clay, glass, and stone products	1,482,611	
Iron and steel and their products	22,930,924	
Metals and metal products, other than iron and steel	587,619	
Miscellaneous industries	5,635,801	
		32,705,117
All other		48,036,332

[2] Ibid , 1900, page 813.

[3] Transactions of the American Institute of Mining Engineers, Vol. X, page 204.

[4] Alabama Geological Survey, Bulletin No. 1.

As shown in Table 2, the value of the manufactures based primarily on minerals mined or quarried amounted to $32,705,117, or 40.5 per cent of the total value of all manufactured products in 1900. The combined value of the products of mines and quarries in Alabama in 1902 and of manufactures in 1900 was $98,109,441, of which amount the manufactures contributed 82.3 per cent and mines and quarries 17.7 per cent.

The average number of wage-earners in Alabama engaged in manufacturing, as reported at the Twelfth Census, was 52,902, and the wages paid amounted to $15,130,419. In 1902 the average number of wage-earners reported as engaged in mining was 19,132, and the wages paid amounted to $10,345,148. The two industries together gave employment to an average of 72,034 wage-earners during the year and paid $25,475,567 in wages, manufactures accounting for 73.4 per cent of the wage-earners and 59.4 per cent of the wages, and mines and quarries accounting for 26.6 per cent of the wage-earners and 40.6 per cent of the wages.

Table 3, compiled from reports of the United States Geological Survey, shows the value of the annual production of the principal minerals of the state from 1889 to 1902.

TABLE 3.—*Value of annual production of principal minerals: 1889 to 1902.*

1899	8,256,462	2,601,609	364,636
1900	9,793,785	2,629,068	533,608
1901	10,000,892	2,587,719	619,423
1902	12,419,666	3,936,812	759,617

[1] Not reported.

Coal.—The coal fields of Alabama form the southern end of the great Appalachian basin, extending from near the northern boundary of Pennsylvania to Tuscaloosa, Ala. The Warrior is the principal field and underlies an area estimated at 7,810 square miles, or nearly ten times the combined areas of other fields in the state, known as the Cahaba and Coosa fields.[1] It is made up of beds in Jefferson, Walker, Winston, Tuscaloosa, Fayette, Marion, Blount, Cullman, and Etowah counties, and contains 23 regular seams, varying in thickness from a few inches to some 16 feet, the total thickness of all seams reaching in some places as high as 115 feet.[2] This is one of the richest coal fields in the world, the quantity of available merchantable coal being estimated at 108,394,000,000 tons—enough at the present rate of consumption to supply the world for over 270 years. The Cahaba field, the area of which has been estimated at 435 square miles, lies in St. Clair, Jefferson, Shelby, and Bibb counties, and the Coosa field, with an area of 415 square miles, embraces portions of Calhoun, St. Clair, and Shelby counties.[3]

The earliest notice of the use of Alabama coal appears in a letter written in 1834.[4] It was then brought down to Mobile from Tuscaloosa in flatboats and sold at the same price as the Liverpool coal, from $1 to $1.50 per barrel. In 1849 but three beds were worked underground, the rest of the coal being taken from the bed of the Warrior river and other streams during the low stages of the water. Before and during the Civil War the industry progressed slowly.

The coal and iron development of the state began about 1870, and with the exception of the panic years 1893–94 each year since has shown an increase in the coal production. The coal counties are Bibb, Blount, Cullman, Etowah, Jefferson, Marion, St. Clair, Shelby, Tuscaloosa, Walker, and Winston; but a little more than one-half of the coal is produced in Jefferson county and over 89 per cent in Jefferson, Walker, and Bibb counties. Cannel, lump, free burning, coking, and gas coals are produced. The manufacture of coke consumed 4,237,491 tons in 1902, 2,760,298 tons of which were made into coke at the mines.[5]

The following table shows the production of bituminous coal in Alabama from 1870 to 1902, inclusive, the figures being compiled from the reports of the United States Geological Survey, "Mineral Resources of the United States:"

TABLE 4.—*Annual production of coal, bituminous: 1870 to 1902.*

1885	2,492,000		

Iron ore.—Almost all of the known ores of iron occur, but (except for small quantities of specular hematites, magnetites, and pyrite) only two are mined, the red hematite—Clinton fossil ore, red ore or Red Mountain

ores—and limonite or brown ores. The red hematite or Clinton fossil ore belt has been the main dependence of the coke-iron industry.

The first iron furnace was built about 1818, a few miles west of Russellville, in Franklin county, and was abandoned in 1827.[1] A furnace was built at Polksville, in Calhoun county, in 1843, the Shelby furnace at Shelby, in Shelby county, in 1848, and one at Round mountain, in Cherokee county, in 1853. These were all charcoal furnaces, and were the only ones in Alabama enumerated by Leslie in 1856. The total product in that year was 1,495 gross tons of pig iron.[2] During the Civil War several new iron enterprises were undertaken, but it was not until about 1870 that the industrial development of the region of which Birmingham is the center set in. The history of Birmingham, which, in 1900, had a population of 38,415, dates from July, 1871, when it was laid out by the Ealyton Land Company.

The following table, compiled from the reports of the United States Geological Survey, shows the production of iron ore from 1889 to 1902:

TABLE 5.—*Annual production of iron ore: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Long tons.	YEAR.	Long tons.
1889	1,570,319	1896	2,041,793
1890	1,897,815	1897	2,098,621
1891	1,986,830	1898	2,401,748
1892	2,312,071	1899	2,662,943
1893	1,742,410	1900	2,759,247
1894	1,493,086	1901	2,801,732
1895	2,199,390	1902	3,574,474

Limestones and dolomites.—The state has extensive deposits of limestone, and 33 quarries were in operation in 1902 in the counties of Blount, Calhoun, Colbert, Dekalb, Etowah, Franklin, Jackson, Jefferson, Lee, Shelby, and Talladega. Naturally the iron furnaces are the largest consumers of limestone as flux, and over 90 per cent of the state's output was for flux and lime burning. A dark, compact limestone occurs near Calera, Shelby county, and a light colored, finely fossiliferous one near Dickson, Colbert county.

Sandstones and quartzites.—The sandstone quarries are in the Potsdam sandstone, which has been opened in Colbert and Talladega counties, and in the sandstones of the Coal Measures. On the line of the Alabama Great Southern Railroad there occurs a yellow sandstone which is sufficiently soft to be cut with an ax, but hardens on exposure.

Clay.—Fire clays are common in the Coal Measures and also in the lowest Cretaceous beds. In the Tuscaloosa formation pottery or stoneware clays are found in Blount, Cherokee, Colbert, Elmore, Tuscaloosa, Pickens, Lamar, Fayette, Marion, and Franklin counties. China clays, kaolin, and ball clays have been found at Rock Run, Cherokee county; Gadsden, Etowah county; Kymulga, Talladega county; Fort Payne, Dekalb county; Chalk Bluff, Marion county; and Pegram, Colbert county. The kaolin found in many portions of the state is in purity all that could be desired. At New Jacksonville and 4 miles northeast of Louina, Randolph county, extensive beds occur. As the reported clay product of the state is only for clay dug or mined and sold as such, it is by no means a measure of the total volume of the product mined, since most of the manufacturers dig their own clay. The extent and diversity of the clay manufactures are shown by the fact that there were 93 establishments in 1900 in the classes of brick and tile and pottery, terra cotta and fire clay products, having a value of $883,129.

All other minerals.—The bauxite belt extends in a northeasterly and southwesterly direction through Cherokee, Etowah, Calhoun, Cleburne, and Talladega counties, with an average width of about 10 miles. It is at the bottom of the Knox dolomite of the Lower Silurian rocks.[3] As early as 1888 ore from near Anniston, in Calhoun county, was identified as bauxite and tested in iron furnaces as to its adaptability for furnace linings.[4] The deposits are all in pockets and are definitely connected with the numerous fault lines of the region. On the expiration of the patents under which the manufacture of aluminum is now held as a monopoly, the manufacture of this metal should be added to the industries of the state, since the state possesses both the ore and cheap power for electric generation. Numerous waterfalls and rapids are available for power, though the abundance and cheapness of coal has much retarded their utilization.

The state possesses all the materials for the manufacture of hydraulic cement, both from natural products (limestone and clay), and from basic slags and lime. Undoubtedly this is destined to be a growing industry. The state now has one Portland cement plant and two slag cement establishments.

Although the present gold yield is trifling, the extent of the auriferous deposits makes it probable that the gold mines of the state may again become of some importance. The state possesses an abundance of low-grade ores, which, with improved methods of concentration and extraction, may be worked profitably. The discovery of gold in Alabama followed soon after the gold discovery in Georgia in 1829, though there were no mint returns from the state until 1840. Gold is found in Cleburne, Clay, Talladega, Coosa, Chilton, Elmore, Tallapoosa, Chambers, and Randolph counties, both in quartz veins and surface gravel. All the earlier

mining was placer, no attention being given to auriferous quartz until later. The chief districts were the Goldville district, Tallapoosa county, and the Arbacoochee district, Cleburne county, the latter at one time employing from 1,500 to 1,800 men in the placer mines. The total value of the gold and silver product to date, excluding that for 1895, which was not separately reported, is, according to the estimates of the Director of the Mint, $450,289, of which $365,300 was produced prior to 1880, the greatest product being between 1840 and 1849.

Graphite has been mined in Cleburne and Clay counties and largely used for furnace linings. The graphite mined in 1902 was from Clay county.

The state is rich in marbles, and a report of their production was made for 1902. A white marble occurs 4 miles west of Talladega and at several other points in the same county, and a black marble is obtained south of Talladega. Variegated marbles are widely distributed in the Tennessee valley, and the mountain limestone at many points is of great purity. The colors are gray with red veins, red and yellow, buff with fossils, and white crystalline clouded with red and black.[1]

Pyrite occurring in a semicrystalline state has been prospected in Clay county, and the pyrite output for 1902 came from this county.

ARIZONA.

Table 1 is a summary of the statistics of the producing mines and quarries of the territory of Arizona for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Copper.	Gold and silver.	Sandstones and quartzites.	All other minerals.[1]
Number of mines or quarries	113	30	74	4	5
Number of operators	158	30	74	4	50
Salaried officials, clerks, etc.:					
Number	445	258	169	9	9
Salaries	$710,183	$399,275	$283,033	$16,775	$11,100
Wage-earners:					
Average number	5,323	3,797	1,442	32	52
Wages	$5,059,065	$3,497,528	$1,498,251	$24,922	$38,364
Contract work	$159,942	$122,337	$37,605		
Miscellaneous expenses	$392,495	$256,753	$114,046	$9,005	$12,691
Cost of supplies and materials	$3,060,521	$2,135,676	$873,091	$50,220	$1,534
Value of product	$11,197,375	$8,279,224	$2,764,677	$107,910	$45,564

[1] Includes operators as follows: Fluorspar, 2; lead and zinc, 1; precious stones, 46 (1 mine); siliceous crystalline rocks, 1.

Arizona ranks third among the states and territories in copper product, with a rapidly increasing output. The territory has extensive mineral deposits, and is famous for the number of its big copper camps—among them being Bisbee, Jerome, Clifton-Morenci, and Globe—and the deposits are not confined to one locality or district. It is also a large producer of gold and silver, and the agatized forest near the town of Holbrook is unique.

There are evidences of rude mining by prehistoric people at a number of points, and it is more than probable that the reduction of copper carbonates was practiced by the aborigines. Lieutenant Cushing discovered ancient oven furnaces in the Salt river valley near ancient copper quarries or pocket mines, with slag and charred grease wood in them, and tests of copper smelting which he made therein, produced copper buttons.[1] It seems likely that the iron ochers, malachites, and azurites were mined in a crude way for pigments, and prehistoric turquoise mines have been found at several points, notably in the Dragoon mountains.[2] The various canyons are said to afford sections of every geological formation known in America and present unsurpassed facilities for the study of the earth's crust to a great depth.[3]

In addition to the mines referred to in Table 1 and which were the source of commercial production in 1902, coal is found in the territory—the Deer Creek or San Carlos field having been known for many years—but on account of its inaccessibility it has not been commercially worked. Extensive deposits of onyx on Big Bug creek, Yavapai county, were located in 1890, since which time the beds have been opened at many places there, and also at Cave creek. The colors are various shades of red, pink, brown, yellow, and green, the latter predominating. These have been worked to a considerable extent but were idle in 1902. Onyx marble in black and white occurs in Kirkland valley and also near Greaterville.[4] Tungsten was discovered in the Dragoon mountains near Benson, Cochise county, in 1896, and the domestic production in 1898 was chiefly from this locality. It is of the manganiferous variety known as hübnerite.[5] It also occurs in the Arivaca district, Pima county; in Mohave county, 16 miles south of Hackberry; and at the Mammoth mine in Pinal county. Gypsum deposits are found near Phoenix and at many other points. In the Santa Rita mountains, Pima county, extensive deposits of a thickness estimated at over 200 feet were discovered by Prof. W. P. Blake in 1896. Nickel has been reported as found in Pima county,[6] and quicksilver ore occurs near Copper Basin, Yavapai county.[7] Bismuth, magnesite, and molybdenum are also found.

There were 381 operators engaged in development work, without production, during the year, of whom 380 were reported for gold and silver and 1 for petro-

[6] Ibid., 1901, Vol. X, page 484.
[7] United States Geological Survey, "Mineral Resources of the United States," 1892, page 161.

leum. These operators gave employment during the year to 386 salaried officials, clerks, etc., who received $459,452 in salaries and 2,246 wage-earners, who were paid $2,329,945 in wages. For work done by contract $197,324 was paid to 317 employees. The miscellaneous expenses amounted to $124,849 and the cost of supplies and materials to $924,313.

Table 2 shows the value of the products of the manufacturing industries of the territory, based primarily upon minerals mined or quarried, and also the value of all products manufactured in Arizona in 1900.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of products.	
All manufactures		$21,315,189
Based upon products of mines or quarries:		
Clay, glass, and stone products	$108,758	
Iron and steel and their products	49,975	
Metals and metal products, other than iron and steel	17,301,417	
Miscellaneous industries[1]	267,722	
		17,727,872
All other		3,587,317

[1] Includes products of 1 establishment under chemicals and allied products.

According to Table 2 the value of the products of manufactures, based primarily upon minerals mined or quarried, amounted to $17,727,872, or 83.2 per cent of the total. The total value of the product of mines and quarries in Arizona in 1902 and manufactures in 1900 was $32,512,564, of which amount mines and quarries contributed 34.4 per cent and manufactures 65.6 per cent.

The average number of wage-earners in Arizona engaged in mining, as reported for 1902, was 5,323 and the wages paid amounted to $5,059,065. The average number of wage-earners engaged in manufactures as reported at the Twelfth Census was 3,266, and the wages paid amounted to $2,369,065. Thus, the two industries together gave employment to an average of 8,589 wage-earners during the year and paid $7,428,130 in wages. Mines and quarries, therefore, gave employment to 62 per cent of the wage-earners and paid 68.1 per cent of the wages, while manufactures furnished employment to 38 per cent of the wage-earners and paid 31.9 per cent of the wages.

Copper.—Within the present area of the United States the first western smelting was done before the Gadsden Purchase, in New Mexico and Arizona, which were not separated until 1863. The copper mines in the Santa Rita mountains near Silver City, N. Mex., were actively worked and their ores smelted early in the century, and the first copper smelting done after the cession of New Mexico and Arizona and before the Civil War was at the Hanover mine. The copper bars were hauled to Galveston, Tex. Shortly afterward copper was mined on the Bill Williams Fork, Arizona, which empties into the Colorado at Aubrey. Most of it was shipped as ore, but there stood at Aubrey in 1895 an old ruined water-jacketed furnace of most odd design. There is no local tradition as to when it was used, and, therefore, it may represent the first attempt at water-jacketed furnaces, as applied to copper smelting.[1]

The Clifton copper district, now generally known as Clifton-Morenci, was discovered about 1865 and has been the scene of continuous mining since 1872. It is the oldest producing copper mining district in Arizona.[2] The first smelting was done in 1874 at the Longfellow mine, with a small Mexican adobe furnace, a blast being supplied by a common blacksmith's bellows.[3]

The second copper district to become productive was the Warren district, better known as the Bisbee mining camp, located in the Mule Pass mountains, Cochise county. It was originally discovered by Henry Warren, but it was not until 1879 that any work of moment was done. The first water-jacket furnace put up in Arizona, of which there is an authentic record, was erected in the autumn of 1880 at the since famous Copper Queen mine, which from that time to the present has been a famous producer.[4]

A great impetus has been given to mining in this district by the success of the Calumet and Arizona Mining Company in developing ore with deep mining. Although nothing of particular value was encountered above a depth of 700 feet, the immense ore bodies opened up below that level have made this property, which became a producer in 1902, one of the future great mines of the world.[5] The deep developments on an extensive scale inaugurated by a number of companies in this camp gives promise of a large increase in the copper product of the territory within the near future.

The Globe district in Gila county has been a large producer since 1882. The original discovery was made many years before, but no locations were made, as copper was at that time valueless in that inaccessible territory.[6]

The Jerome district has been made famous by the United Verde, which was originally a small gold and silver mine. The mine is opened on a single monstrous lens of sulphide ore, in slate, said to be at least 1,900 feet long, with an extreme width of 600 feet and having a dip of 72 degrees. The ore, owing to excess of sulphur, frequently catches fire from spontaneous com-

[6] Transactions of the American Institute of Mining Engineers, Vol. XV, page 60.

bustion, and the mine has suffered much from fires. Owing to the precipitous nature of the ground and the location of the smelter and town of Jerome in a narrow gorge, with the smelter squarely on top of the mine, the ore is handled in a somewhat unique fashion. All ore is sent to the 500-foot level and thence trammed out through a 1,300-foot tunnel to the roast yard. When roasted, the ore is trammed back through the tunnel into the mine and hoisted through the shafts to the smelter.[1]

Besides these big camps, there are a number of others which would be notable in any other section of the country. The Ajo copper mines in Yuma county were among the first discovered.

Gold and silver.—Ores of gold and silver are widely distributed and the territory has a number of notable mines. The bonanza of the Silver King mine of Pinal county, discovered in 1874, is famous in the annals of the territory.[2] It is credited with the payment of $2,000,000 in dividends. The first locations in Tombstone, Cochise county, were made in 1878, and up to January 1, 1882, or in less than three years, the gold and silver output of the camp aggregated $7,359,200, of which over $3,000,000 had been disbursed in dividends.[3] Following the decline in the price of silver, and partly on account of difficulties experienced in draining the mines at Tombstone, they closed down and remained idle for a number of years. Active work was resumed in the Tombstone mining district in 1901–2, nearly all the important claims having been combined in the hands of one company.[4]

The Congress mines in Yavapai county were first opened in 1887, and were successfully operated until September, 1891, when they were closed, and the property remained idle until March, 1894. The mines have now been opened to a depth of 1,300 feet.[5]

The La Fortuna and the King of Arizona, of Yuma county, the Mammoth, of Pinal county, and the famous Vulture, of Maricopa county, which in years past was one of the great wealth producers of the Southwest, are but a few of the mines which have helped to make the reputation of Arizona.

Table 3, compiled from the annual reports of the Director of the Mint, shows the annual production and value of gold and silver in the territory of Arizona from 1889 to 1902, inclusive.

1900	202,856	4,193,400	2,995,500	[2]1,857,210
1901	197,515	4,083,000	2,812,400	[2]1,687,440
1902	198,933	4,112,300	3,048,100	[2]1,612,843

[1] Estimates of the Director of the Mint, value of refined product, silver at coining value. The values given in Table 1 are the values at the mine.
[2] Commercial value.

All other minerals.—Fluorspar was mined by two operators in Yuma county.

Lead ore was only produced by one mine operated as such, though the territory produces considerable lead as a by-product of its gold and silver ores.

The production of the territory classified under precious stones comprises, in the order of their values, turquoise, silicified wood, garnet, and peridot or chrysolite. Turquoises were found worn by the natives on the first entry of Marcos de Niza into the country in 1539, and prehistoric turquoise mines have been found at several points. Turquoise mining was almost unknown in the United States when the census of 1890 was taken, but it is now a regular industry.. The present production of the territory comes from Mohave county. The agatized forest of Arizona, located in Apache county, not far from the town of Holbrook, affords a wealth of beautiful ornamental stone unequalled anywhere in the world. The logs and trunks of ancient trees, converted into agate and chalcedony of mingled shades, when cut and polished, give most exquisite effects of line and color. The yield reported in the last four years was $2,000 in 1898, $3,000 in 1899, $6,000 in 1900, and $7,000 in 1901.

Bohemian or pyrope garnets are found in several places in northern Arizona, and are sometimes called Arizona rubies. They are found generally around ant hills and scorpion holes, where they have been brought up and thrown out by the insects. The production of peridot or chrysolite is reported from Gila county, the specimens being found and brought in by Indians and others. The sandstone quarried was used chiefly for building stone, and the siliceous crystalline rock or granite quarried was all dressed for monumental work.

ARKANSAS.

Table 1 is a summary of the statistics of the productive mines and quarries in the state of Arkansas for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Limestones and dolomites.	Sandstones and quartzites.	Oilstones and whetstones.	Bauxite.	Siliceous crystalline rocks.	All other minerals.[1]
Number of mines or quarries	120	53	13	18	4	19	3	10
Number of operators	131	33	12	17	3	3	3	60
Salaried officials, clerks, etc.:								
Number	210	146	16	11	2	13	2	20
Salaries	$191,528	$148,113	$7,864	$5,806	$1,050	$10,875	$1,650	$16,170
Wage-earners:								
Average number	2,944	2,574	119	111	23	30	10	77
Wages	$1,945,479	$1,780,061	$43,680	$52,170	$10,615	$14,504	$4,260	$40,189
Contract work	$860	$485				$375		
Miscellaneous expenses	$95,481	$82,949	$1,716	$1,530	$685	$4,175	$945	$3,481
Cost of supplies and materials	$244,379	$177,716	$32,579	$7,915	$1,625	$10,602	$650	$13,292
Value of product	$2,840,341	$2,539,214	$113,163	$85,917	$21,275	$13,920	$12,115	$54,737

[1] Includes operators as follows: Asphaltum and bituminous rock, 1; fuller's earth, 2; gold and silver, 1; manganese ore, 2; marble, 1; mineral pigments, crude, 1; phosphate rock, 1; precious stones, 50 (no mines); slate, 1.

The chief mineral product of the state is bituminous coal, though the amount is not large. The mining of bauxite is a new and growing industry. The oilstones and whetstones of the state, made from novaculite, have a high reputation.

In addition to the minerals referred to in Table 1, there are other important mineral products of which the state has been a producer, though they were not reported as being mined in commercial quantities in 1902, and still others that exist in such quantities as to justify the belief that with development or with improved transportation facilities they may add to the wealth of the state. Among these are: Antimony, which is said to occur in sufficient quantity in Sevier county to be of commercial value;[1] Portland cement, which was formerly manufactured at White Cliffs from the chalk deposits of southwest Arkansas, but which was not produced again until 1903, the remodeling of the plant being in progress in 1902; copper, which, in the form of carbonates and sulphates, has been found in many counties, notably in Searcy, and which was partially developed in 1885;[2] and iron ores, which are found at many points in the state, but not in extensive deposits.

The tardiness of the development of the zinc and lead deposits is due in part to the topography of the district, through which there have been no railroads until recently. The zinc bearing ore district of north Arkansas is a part of the Missouri district. The first active mining was in 1875, when a smelter was erected at Calamine, Sharp county, for the reduction of carbonate ores. The enterprise was not successful, and was abandoned. In 1880 a lead smelter was erected at Leadhill and was operated for a short time. The next development of note was in 1882, when a smelter was built and a town laid out at Boxley, Newton county. Operations were continued for a year, but the long wagon haul of 95 miles to the nearest railroad was too great a tax, and operations were suspended. The Morning Star mine, in Marion county, was discovered in 1884. The exhibitor of a monster piece of zinc carbonate, which weighed 12,750 pounds, from this mine, was awarded a gold medal at the Chicago Columbian Exposition. Smithsonite, calamine, and sphalerite ores are found, the last named being the most frequent in occurrence.[3] Argentiferous lead has been found in Pulaski, Sevier, Polk, Montgomery, and Howard counties.[2] Extensive beds of gypsum, often crystallized into selenite, are found in Pike, Bradley, and Howard counties;[2] kaolin is known to occur in Pike, Pulaski, Saline, and Ouachita counties;[4] lithographic stone of excellent quality occurs near Little Rock;[5] soapstone is found in Saline county, and has

[2] Products and Resources of Arkansas, by D. McRae, 1885, page 11.

[3] Transactions of the American Institute of Mining Engineers, Vol. XXXI, page 396.

[4] Bureau of Mines, Manufactures, and Agriculture of Arkansas, Fourth Biennial Report, page 110.

[5] United States Geological Survey, "Mineral Resources of the United States," 1889-90, page 519.

been quarried to some extent;[1] nickel occurs sparingly in Saline county; and oil and gas have been found in small quantities.

Development work on deposits of asphaltum, gold and silver, and natural gas was reported by 3 operators. The total expense for development work was $5,800; of this amount $4,500, expended for work done by contract, furnished employment to 5 employees.

The following table shows the value of the products of those manufacturing industries of the state in 1900 that were based primarily upon minerals mined or quarried, and also the value of all products manufactured in Arkansas during that year:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$45,197,731
Based upon products of mines or quarries:		
Clay, glass, and stone products	$652,676	
Iron and steel and their products	456,814	
Metals and metal products, other than iron and steel	229,697	
Miscellaneous industries	876,703	
		2,215,890
All other		42,981,841

According to the foregoing table the value of the products of manufactures, based primarily upon minerals mined or quarried, amounted to $2,215,890, or 4.9 per cent of the total. The combined value of the products of mines and quarries in Arkansas in 1902 and manufactures in 1900 was $48,038,072, of which amount manufactures contributed 94.1 per cent and mines and quarries 5.9 per cent.

The average number of wage-earners in Arkansas engaged in manufacturing at the Twelfth Census was 26,501 and the wages paid amounted to $8,686,291. In 1902 the average number of wage-earners reported as engaged in mining was 2,944 and the wages paid amounted to $1,945,479. The two industries, therefore, gave employment to an average of 29,445 wage-earners during the year and paid $10,631,770 in wages. Manufactures alone gave employment to 90 per cent of the wage-earners, who received 81.7 per cent of the wages, while mines and quarries furnished employment to only 10 per cent of the wage-earners, who received 18.3 per cent of the wages.

Table 3 shows the value of the annual production of the principal minerals of the state from 1890 to 1902.

[1] Products and Resources of Arkansas, 1885, page 13.

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Limestones and dolomites.	Sandstones and quartzites.
1890	$514,535	$18,360	$25,074
1891	647,560	20,000	20,000
1892	666,230	18,000	18,000
1893	773,347	7,611	3,292
1894	631,988	38,228	2,365
1895	751,156	47,376	13,228
1896	755,577	30,708	1,400
1897	903,993	44,222	3,161
1898	1,238,778	54,373	24,825
1899	989,383	71,965	73,616
1900	1,653,618	71,407	104,923
1901	2,068,613	68,319	62,825
1902	2,539,214	113,163	85,917

Coal.—Practically no coal was mined prior to 1870, though it has been stated that some was taken out that year. Mining on a commercial scale can hardly be considered to antedate 1883, and from that time to 1887 the production was almost entirely confined to Johnson and Polk counties.[2] Most of the coal mined is of a very superior quality.

In 1902 coal production was reported from Sebastian, Johnson, Franklin, Pope, Scott, Logan, and Ouachita counties, over 68 per cent of the product being from Sebastian county alone.

Table 4 shows the annual production of bituminous coal in Arkansas from 1880 to 1902, inclusive, the figures being taken from the 1902 report of the United States Geological Survey.

TABLE 4.—*Annual production of coal, bituminous: 1880 to 1902.*

1889	279,584	1902	1,943,932
1890	399,888		

Limestones and dolomites.—Limestone occurs quite generally throughout the state.[1] The production in 1902 was valued at $113,163, of which $82,853 was for stone made into lime and $22,510 for crushed stone used for roadmaking and railroad ballast. The balance was for

[2] Arkansas Geological Survey, 1888, Vol. III, page 35.

riprap, building stone, curbing, and other uses. A marked increase is shown for 1902 in the value of limestone crushed for roadmaking.

Sandstones and quartzites.—The whole western side of the state is underlaid with a metamorphosed sandstone, and quarries have been opened in Carroll, Conway, Crawford, Independence, Johnson, Polk, Pope, Pulaski, Sebastian, Washington, and White counties.[1] Nearly one-half of the sandstone product was used for railroad ballast.

Oilstones and whetstones.—In the Washita mountains west of Little Rock are large masses of novaculite from which the finest whetstones, known in the market as "Arkansas" and "Washita" stones, are made. The principal quarries are on Quarry or Whetstone mountain, near Hot Springs, Garland county, though the stone is also quarried in Saline county. The stones were first put on the market about 1840, in which year a quantity of rough stone was shipped to Europe and cut into whetstones. The next year a small quantity was cut up and manufactured into oilstones at St. Louis, and since that time the demand has continued steady.[2] The Arkansas stone is a true novaculite, an average analysis showing it to contain 99.5 per cent of silica.[3]

Bauxite.—The bauxite beds of Pulaski county were discovered by John C. Branner, state geologist, in 1887. At the time the rock was identified it was being extensively used for roadmaking. In some cases it contains so much iron that the beds have been prospected with a view to using the material as an iron ore. In other cases it contains so much silica and so little water that it is not distinguishable by analysis from ordinary kaolin, and the varieties grade insensibly into each other with no line of demarcation. It has been found in Arkansas only in Tertiary areas and in the vicinity of eruptive syenites. The beds vary greatly in thickness, the thickest found being 40 feet.[4]

The production of bauxite since 1899, when it was first reported, is shown in the following table:

TABLE 5.—*Annual production of bauxite: 1899 to 1902.*

[4] Transactions of the American Institute of Mining Engineers, Vol. XXX, page 347.

All other minerals.—Asphaltum was reported from Pike county in 1902 by one operator.

The only states producing fuller's earth in 1902 were Arkansas and Florida, the Arkansas product coming from Saline county. It was first discovered in the United States at Quincy, Fla., in 1893, where the greater part of the output of the United States has since been obtained.

The Arkansas granite, whether as paving stone or as building material, is unsurpassed and has been used to a considerable extent within and without the state.[5] The Pulaski county quarries, three in number, were the only ones reported as in operation in 1902, with a product valued at $12,115. This is a decline from former years, the product in 1900 having been valued at $62,500.

Manganese ore was mined in 1860, though the first report of output was made in 1868. The industry increased steadily, and a decade ago Arkansas was the principal manganese producing state. Its maximum output was in 1892, when the quantity reported was 6,708 tons. Since 1896 the output has declined rapidly. The entire production has come from the Batesville district, Independence county. There are vast deposits in Polk county and also in Izard county, but the high phosphorous contents, distance from railroad, and expense of mining have rendered much of it unmarketable.[6] The annual production of this mineral from 1881 to 1902, inclusive, is shown in the following table:

TABLE 6.—*Annual production of manganese ore: 1881 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Long tons.	YEAR.	Long tons.

Although Arkansas does not take high rank as a producer of the precious metals, yet gold and silver occur in many localities. Argentiferous galena is found in Pulaski, Sevier, Polk, Montgomery, and Howard counties.[7] Gold and silver mines in Polk county were prospected as early as 1860, and mining and development work was reported in 1902, with production from one mine in Polk county.

[5] Bureau of Mines, Manufactures, and Agriculture of Arkansas, Sixth Biennial Report, 1899–1900, page 167.
[6] Products and Resources of Arkansas, 1885, page 10.
[7] Ibid., page 11.

Marble is found in Independence, Izard, Marion, Searcy, Carroll, Saline, Newton, and Madison counties. It is of fine texture and various colors—pink, gray, white, and black.[1] The value of the product reported for the state in 1899 was $3,410. A small amount was also reported in 1901. The production reported for 1902 was from Carroll county.

There are extensive deposits of ocher found near Monticello, in Drew county, and in Clay county. There are also deposits in southern Arkansas and in other parts of the state. The production of crude mineral pigments reported for 1902 was from Clay county.

Phosphate beds occur—associated with what is known as the Sylamore sandstone and the Eureka shale—in the vicinity of Hickory valley, in the neighborhood of Cushman, Independence county, and at other points. The production reported for 1902 was from Independence county. Phosphate beds are also found in connection with the beds of the Ouachita uplift, and are known to occur in some of the Cretaceous beds of the state. The Cretaceous marls of the southwestern portion of the state are very like the Greensand marls of New Jersey, and are in all probability equally suitable for fertilizers.[2]

As precious stones, the quartz crystals of Hot Springs, Garland county, are famous, and their collection for sale to tourists has been an industry of many years' standing. Though not large enough for art purposes, they are beautiful as specimens. They are also found in Montgomery and Saline counties.

Roofing slate is found in Montgomery, Pike, Polk, Pulaski, Saline, and Sevier counties. The production reported for 1902 was from Montgomery county.

Cost of supplies and materials	$5,673,755	$2,966,102	$1,479,528	$210,729	$211,163	$248,894	$115,429	$111,564	$80,967	$1,350	$248,029
Value of product	$28,870,405	$15,473,091	$4,873,617	$2,370,994	$1,599,663	$1,295,740	$1,137,679	[3]$521,093	$469,016	$101,353	$1,028,159

[1] Includes operators as follows: Cement, 2; chrome ore, 1; clay, 6; coal, bituminous, 10 (including 2 operators in Alaska); gypsum, 1; infusorial earth, tripoli, and pumice, 1; lithium ore, 2; magnesite, 1; manganese ore, 3; marble, 5; mica, 1 (10 mines); mineral pigments, crude, 2; natural gas, 15 (29 wells); precious stones, 47 (31 mines); slate, 1; sulphur and pyrite, 2; and talc and soapstone, 1.

[2] Includes 1 operator in Hawaii.

[3] Exceeds United States Geological Survey report by $24,250, the value of limestone quarried for cement.

Gold is by far the most important mineral product of the state. The production of gold in 1902 exceeded in value that of all other minerals combined, being approximately $15,000,000, which was nearly one-fifth of the refined gold product reported for the United States (including Alaska). Petroleum was the mineral product next in value, borax was third, copper fourth, and quicksilver fifth.

A large number of minerals are known to exist in the state that were not mined in commercial quantities in 1902: Asbestos occurs in Tulare, Yolo, Butte, Placer, San Diego, Eldorado, and Mariposa counties in small quantities. Barytes has been observed in Calaveras, San Bernardino, Plumas, and Inyo counties. Buhrstones are known to exist in Inyo county. Corundum is found in drift at San Francisco pass, Los Angeles county, and feldspar is obtainable in Mariposa county. Iron ore exists in Placer, Sierra, Eldorado, Napa, Shasta, Amador, Inyo, Alameda, Del Norte, Butte, Alpine, and Nevada counties. Marl is found in various localities; nickel is obtainable in San Benito, Kern, Monterey, Tuolumne, and Mono counties; and cobalt occurs in Los Angeles county. Tin ore is known to exist in San Bernardino county, as well as lead, which also occurs in small deposits in Mono, Shasta, Amador, and other counties. Zinc is found in Tulare and San Mateo counties.[1] A deposit of fuller's earth was opened in 1898 near Bakersfield, in Kern county.[2]

In addition to the productive mines, quarries, and wells for which statistics are shown in Table 1, considerable development was done in 1902. The operators engaged in such work exclusively, reported an expenditure of $2,925,700 for salaries and wages, contract work, supplies and materials, and miscellaneous expenses. Of this amount, 81.3 per cent was expended upon gold and silver mines, and 17.5 per cent upon petroleum interests, the remainder being for limestones and dolomites, quicksilver, iron ore, siliceous crystalline rocks, borax, asphaltum, bituminous rock, and marble.

Table 2, showing the annual value of production of the principal minerals from 1890 to 1902, except copper ore, for which values can not be obtained, has been compiled from the United States Geological Survey, "Mineral Resources of the United States," and from reports of the Director of the Mint.

[1] United States Geological Survey, "Mineral Resources of the United States," 1887, pages 704 to 707.

[1] Estimates of the Director of the Mint, coining value.
[2] Value not reported—307,360 barrels.
[3] Commercial value.
[4] Census figures, except for gold and silver.

Of the principal minerals, bituminous coal and siliceous crystalline rocks are the only ones for which the value of production was smaller in 1902 than in 1890. The production of petroleum, which is rapidly replacing coal as a fuel, has very largely increased since 1890. Gold has increased from $12,500,000 in 1890 to $16,792,100 in 1902, but the value of the silver production has fluctuated. There has been a steady increase in the production of building stone since 1896, and in 1902 quarrying stood among the important industries of the state. The value of siliceous crystalline rocks in 1902 was $1,137,679, or more than one-half the value of all stone quarried. Limestone, sandstone, marble, and slate were also produced, ranking in value of product in the order named.

Gold and silver.—In California gold is found chiefly in a belt from 20 to 60 miles wide extending along the lower slopes of the Sierra Nevadas a distance of about 700 miles.[1]

The principal gold regions were in Amador, Butte, Calaveras, Eldorado, Fresno, Inyo, Mariposa, Mono, Nevada, Placer, Plumas, San Bernardino, San Diego, Shasta, Sierra, Siskiyou, Trinity, and Tuolumne counties.[2] California gold averages about 88 per cent fine (United States Mint). Many analyses, however, ran up to 95 per cent or higher.[3] The gold occurs principally in auriferous gravels, high or deep gravels, and in gold bearing quartz veins.[4]

The occurrence of placer gold in California was discovered near the Colorado river in San Diego county as early as 1775.[5] On January 19, 1848, it was found near Coloma, Eldorado county, on Col. John Sutter's land, by James Wilson Marshall. The California legislature, in 1887, honored the memory of Marshall by appropriating $5,000 for a monument over his grave in Coloma.

[1] Treatise on Ore Deposits, by J. A. Phillips and Henry Louis, page 741.
[2] Dana's Mineralogy, page 1095.

[4] Ore Deposits of the United States, by James F. Kemp, pages 243 and 248.
[5] California State Mining Bureau, Fourth Annual Report, 1884, page 217.

The first deposit of California gold in a United States mint was made on December 8, 1848, and in 1850 an assay office was established at San Francisco. At the outset the precious metal was obtained by alluvial washings, but in 1852 quartz mining became prominent, and has now largely supplanted the placer operations.

In 1849, the first year after its discovery by Marshall, the production of gold in California was $5,000,000. Rapidly increasing year by year, the production in 1853 was nearly $60,000,000. Since then it has diminished until in 1866 the amount was but $27,000,000, and from 1881 to 1888 it varied from $18,200,000 to $12,750,000.[6] During the last ten years, up to 1902, the California gold production has been more steady, the average yearly value of product for this decade being $15,106,148.

Silver mining interests in the state are small as compared with gold. Deposits of silver chloride, occurring in fissure veins, small fractures, and pockets in liparite and tufaceous sandstone, are disseminated sparingly in the southwestern and other portions of the state.[7]

The production of silver in 1902 was reported in 27 counties, the principal of which are Shasta, Kern, San Bernardino, Calaveras, Mono, Fresno, and Inyo in the order named.[8]

The following table of annual production in fine ounces of gold and silver is compiled from the estimates of the Director of the Mint:

TABLE 3.—*Annual production of gold and silver: 1890 to 1902.*

YEAR.	Gold (fine ounces).	Silver (fine ounces).	YEAR.	Gold (fine ounces).	Silver (fine ounces).
1890	604,687	900,000	1897	707,160	474,400
1891	609,525	750,000	1898	756,483	642,300
1892	580,500	392,200	1899	735,194	824,300

[8] Report of the Director of the Mint, 1902, page 79.

Petroleum.—The area of petroleum bearing land has proved much greater than was at first supposed, and a good demand has stimulated prospecting in new territory. Oil bearing territory has even been found to extend under the ocean, and at Summerland, wells have been driven 200 feet from shore. The saving by the use of oil in the generation of steam for electric light and power plants and as a locomotive fuel, estimated at from 30 to 50 per cent, has caused it to replace coal, especially in sugar and other manufactories. Petroleum has also been quite extensively introduced as a household fuel. In the region of Los Angeles successful experiments with it have been made in improving the public highways. When sprinkled on a dry road the hot oil combines with the dust and forms a hard surface, durable and dustless.[1]

The production of petroleum has increased from a product of 303,220 barrels, valued at $356,048, in 1889, to 13,984,268 barrels, having a value of nearly $5,000,000, in 1902. This increase is best illustrated in the following table, compiled from reports of the United States Geological Survey, "Mineral Resources of the United States":

TABLE 4.—*Annual production of petroleum: 1891 to 1902.*

YEAR.	Barrels (42 gallons).	YEAR.	Barrels (42 gallons).	YEAR.	Barrels (42 gallons).
1891	323,600	1895	1,208,482	1899	2,642,095
1892	385,049	1896	1,252,777	1900	4,324,484
1893	470,179	1897	1,903,411	1901	8,786,330
1894	705,969	1898	2,257,207	1902	13,984,268

[1] United States Geological Survey, "Mineral Resources of the United States," 1899, page 156.

California oil is generally dark in color and heavy in specific gravity, differing from the Pennsylvania and Ohio product in that its base is asphaltum rather than paraffin. This quality makes it very valuable for the manufacture of varnishes, lubricants, etc. In some instances the oil is a semiviscid bitumen called maltha or brea. This substance, when refined as petroleum, reveals a considerable by-product of asphaltum, which has a limited market on the Pacific coast for paving purposes. Gasoline and a very satisfactory grade of lubricating oil are produced, but the illuminating product does not compare favorably with the eastern production.

Borax.—The Great Basin, lying between the Wasatch and the Sierra Nevada mountains, forms an alkaline plain which has been found to contain valuable borax deposits.[2] This plain is marked by desiccated lake beds in which certain salts derived from the rocks of their watersheds have concentrated. These dry lakes and alkali marshes may be found in all degrees of saturation, often covered with a crust beneath which is deep water or slime.

The mineral borax was discovered in Borax Lake, Lake county, by Dr. John A. Veatch, in 1856, but no attempt at working the deposit was made until 1864. The following table of borax production in the state, illustrates the growth, value, and locality of the industry up to 1890:[3]

[2] The Mineral Industry, Vol. I, 1892, page 43.

[3] California State Mining Bureau, Bulletin No. 24, May, 1902, "The Saline Deposits of California," by Gilbert E. Bailey, E. M., Ph. D., page 39.

TABLE 5.—ANNUAL PRODUCTION AND VALUE OF BORAX: 1864 TO 1889.

YEAR.	Production (pounds).	Value per pound (cents).	Value per ton (dollars).	Total value (dollars).	Remarks.
1864	24,304	39	780	9,478	Lake county, Borax Lake.

1889	1,930,000	7	140	145,473	San Bernardino county, Calico district; Ventura county.

Lake, San Bernardino, Inyo, and Ventura counties are the principal fields of borax deposits. In the Calico district, San Bernardino county, borate of lime is taken from a fissure vein and this is said to be the only place in the world where deep mining for borax is carried on.[1] These deposits, discovered in 1882, are very productive, and the workings have been extended to a considerable depth.

An interesting feature in connection with borax production is the phenomenal decrease in the value from 39 cents per pound to about 7 cents at the present time. The deposits of California are very extensive, and in some instances only an increased demand and a consequently higher price are necessary to make them profitable workings.

Copper ore.—Copper was not mined in California until 1860,[2] although the mineral was discovered in Los Angeles county as early as 1840. The period from 1860 to 1867 was one of considerable activity, and thousands of tons of copper ore were shipped to the Atlantic coast and Europe for reduction. Then occurred a depression in copper production in California due to a fall in prices, and for over fifteen years copper remained as one of the minor minerals of the state. In 1895 and 1896, when the rich deposits of Shasta county began to be worked with success, there occurred a general revival of copper mining in the entire state, and from 1897 copper production has been accounted one of the leading industries of California.

Copper deposits are said to occur in almost all of the counties of the state, but the principal regions of commercially important production are as follows:[3] Shasta county, the Coast Range, the Sierra Nevada, and the mineralized deserts of southeastern California. The Shasta county copper mines, in the north central part of the state, are the principal source of production, and the copper belt of the western slope of the Sierras, with its 400 miles of almost continuous copper deposits, occupies second place. The Coast Range copper deposits have been developed only in Del Norte county, but superficial prospecting displays the existence of the mineral throughout almost the entire length of the range. The copper deposits of southern California are scattered and do not form a regular chain or belt as do those of the three more important localities.

Quicksilver.—The American production of this mineral is principally in California. Cinnabar or sulphide of mercury was discovered there in 1845, and mining began at New Almaden in 1850.[4] In the Coast Range for 100 to 150 miles north and south of San Francisco occurrences of this ore are found to exist, most generally in irregular bodies distributed through metamorphic rocks of Cretaceous age. Quartz, calcite, and magnesite are the usual gangue minerals. In 1902 production was reported in nine counties in the state, amounting to $1,295,740 in value, of which $1,228,498 was the value of refined product in flasks of 76½ pounds each, and $67,242 the value of crude cinnabar not concentrated.

Siliceous crystalline rocks.—The quarrying of siliceous crystalline rocks in California began as early as 1853,[5] and in 1902 this industry ranked sixth in value of products among the mineral industries of the state.

Limestones and dolomites.—The total production of limestone in 1902 was somewhat less than that of the preceding year, due largely to the great decrease in its use as a paving material. Considerable interest centers in the use of limestone in the manufacture of cement, and in 1902 an amount valued at $24,250 was reported as used for this purpose.

Sandstones and quartzites.—The value of sandstone product reported in 1902 was $462,328, the largest production in any year during the period 1890 to 1902. During the last five years the quarrying of this stone has advanced from a minor industry to a position of importance in the state, and in 1902 California ranked fifth in sandstone production in the United States. Extensive quarrying was begun in 1898 to supply rough stone for breakwaters and jetties, and for several years was used principally for this purpose. In 1901 and 1902 its use for building purposes became of most importance.

Marble.—The value of production of marble in 1902 amounted to $92,298, or more than that of any other year since 1892. Of this amount $33,198 was reported as the value of the rough, unfinished marble for all purposes and $55,000 as that of marble used in interior decoration, the remainder being the value of the marble intended for monumental and ornamental work. The deposits are principally in the southern portion of the state, although occurrences are reported in the extreme north. California onyx is the most valuable of the marbles quarried, and is generally found in proximity to hot springs or associated with minerals known to have resulted from such waters.[6]

Slate.—A roofing slate, blue-black in color, with good cleavage, is produced in Eldorado and Mariposa counties, but statistics can not be given without disclosing the operations of individual establishments.

Asphaltum and bituminous rock.—The mineral asphaltum was known to exist in California long before it was commercially produced; there is a record of its use by the Indians and the Catholic fathers. The discovery of bituminous rock is said to have been in 1868 near Santa Cruz, and its use at that time, although local, was considered a success. The hard asphaltum occurs chiefly in Santa Barbara and Ventura counties; the

[6] Ibid., Twentieth Annual Report, Part VI, page 288.

liquid or maltha, in Santa Barbara and Kern, and the asphaltic sandstone and bituminous rock in Monterey, San Luis Obispo, and Santa Cruz counties. California asphaltic localities are thus in the vicinity of the Coast Range and south of San Francisco bay. A valuable and interesting deposit of the hard variety exists in Goleta, in Santa Barbara county. The asphaltum appears in a ledge washed by the Pacific ocean, and is exposed for a distance of several hundred yards. It occurs in pockets of from 1,500 to 3,000 tons, and is almost pure, containing only a small percentage of sand. Asphaltum is chiefly used as a rust proof coating for submarine and underground iron pipes. The commercial production of the mineral began in California in 1888, and flourished for two years, but the industry did not prove a financial success at the outset, and in 1890 no production was reported.[1] A resumption of activity in 1891 was more successful. Since that time there has been a general increase of production, and in 1902 California ranked first in this industry.

Coal.—Coal was discovered in the state during 1852, although no productive mining occurred until after 1860. In 1902 the production amounted to 84,984 short tons, principally lignite, which is a decrease of 66,095 short tons from the preceding year and less than one-half the production of 1900. The discovery and utilization of extensive oil fields is the principal cause of the marked decrease in coal production.

Natural gas.—Natural gas was known to exist in California as early as 1854, and the Court House well near Stockton, in San Joaquin county, was bored prior to 1858.[2] The principal localities in which gas was produced commercially during 1902 were Sacramento, San Joaquin, Santa Barbara, and Los Angeles counties. Important occurrences have been observed in Contra Costa, Fresno, Humboldt, Lake, Marin, Mendocino, Solano, Sonoma, Tehama, Tulare, and other counties. In some instances the gas is found in connection with petroleum, while in other cases it bubbles up in mineral springs or in artesian water flows.[3] The accumulation of very large high-pressure reservoirs of natural gas in this region has probably been prevented by the folded formation of the strata and the occurrence of earthquakes of greater or less severity. It is thought probable that larger quantities may be stored at greater depth than has yet been mined. The production of California natural gas in 1902 is valued at $120,648, in which is included gas to the value of $31,604, obtained from petroleum wells.

Manganese ore.—The first mining of manganese ore in California was at Corall Hollow in Alameda county in 1867.[4] Other deposits were known to exist, but for a number of years they were not considered to be of commercial importance. In 1902, however, several of these were opened up. The total product reported was 846 long tons, valued at $10,175, a very large increase when compared with the preceding years. The manganese ore is used principally in the manufacture of chlorine gas for working sulphureted gold ores.

The following are the minerals grouped in Table 1 under "all other minerals":

Cement.—The California production in 1902 was entirely of the Portland cement and was reported only in San Bernardino and Solano counties. Two establishments were in operation in 1902, and the production was much larger than that of previous years.

Chrome ore.—Chromic iron ore occurs in more than one-half the counties of California,[5] but the commercial production in 1902 was all reported by the Mt. Shasta chrome mine near Simms in Shasta county. This was the only active mine in the United States during 1902, and the product was sold principally in its crude state for furnace lining.

Clay.—Practically inexhaustible beds of clay, some of which is of very good quality, are found in California, accessible by railroad.[6] Extensive utilization of these vast deposits is somewhat discouraged by heavy eastern and European importations of clay manufactures at so low a rate as to curtail profitable local manufacture. The quantity produced in 1902 was somewhat less than that reported by the Geological Survey for the previous year, but an increase in the value of products, as compared with 1901, indicates that better prices prevail. In 1902 a total of 23,483 short tons, valued at $24,445, was produced; while in 1901 a production of 28,085 short tons, valued at $22,535, was reported.

Gypsum.—This mineral is commercially produced by one company in Los Angeles county. Of the product reported in 1902, 9.4 per cent was sold in crude form, 6.4 per cent was ground into land plaster, and 84.2 per cent was calcined into plaster of Paris.

Infusorial earth, tripoli, and pumice.—A deposit of infusorial earth of diatomaceous origin is found in Santa Barbara, and a considerable production was reported in 1902, which was all sold in the crude form.

Lithium ore.—Lepidolite and amblygonite are the principal lithium minerals[7] obtained. They are used chiefly in the manufacture of lithium effervescent tablets and lithium carbonate for the preparation of mineral waters for medicinal purposes. The California product, obtained only in San Diego county, is nearly all shipped to New York for treatment, and constitutes a very large portion of the United States production.

Magnesite.—Although this mineral occurs in several states it is mined commercially only in California.[8] There is an abundance of the ore in the state, but dis-

tance from large manufacturing centers prevents shipment under present conditions. The production during 1902 was all mined in Tulare county, and is reported by one company.

Mica.—The operations during 1902 were mostly development work, although a small production was reported from Ventura county. The product was entirely scrap mica, which was ground for lubricants and other purposes.

Mineral pigments, crude.—Yellow ocher is produced in Calaveras county, near Valley Springs, and in Stanislaus county. There were but two companies operating in California in 1902.

Precious stones.—The principal precious stones reported in California are turquoise and tourmaline, with chrysoprase and gold quartz in minor quantities, the total production in 1902 being valued at $65,000. Diamonds have been found at irregular intervals,[1] principally by placer gold miners, but every discovery thus far has been purely accidental, and none was reported during the census year. Quartz crystals have been found near Placerville, and chiastolite macle, or crossstone, has been obtained in Madera county, but no product was reported for 1902.

Sulphur and pyrite.—A considerable production of pyrite was reported from Alameda county. The ore averages from 49 to 50 per cent sulphur and is chiefly used for the manufacture of sulphuric acid.

Talc and soapstone.—Serpentines and soapstone occur in Los Angeles county, on Santa Catalina Island, and were mined in considerable quantity in 1902.

Cost of supplies and materials	$7,006,846	$5,603,452	$1,039,831	$137,450	$68,708	$36,196	$21,440	$38,221	$5,608	$4,720	$3,010	$3,000	$45,210
Value of product	$40,603,286	$29,655,974	$8,397,812	$1,084,424	$484,683	$366,161	$203,700	$71,411	$67,434	$66,023	$48,125	$22,398	$135,141

[1] Includes operators as follows: Cement, 1; gypsum, 1; natural gas, 3; precious stones, 25 (no mines); tungsten, 3.

The state is notable for its range of mineral wealth. In the production of both gold and silver, it is first among the states and territories producing the precious metals in 1902, over 36 per cent of the refined gold product and over 27 per cent of the silver product reported for the United States (including Alaska) being contributed by this one state. In coal it ranked eighth among the 29 coal producing states, tenth among the 25 states producing iron ore, and ninth among the 18 petroleum producing states. Moreover, it produced all of the uranium and vanadium and almost all of the tungsten reported.

In addition to the minerals referred to in Table 1, there are found within the state—although these minerals were not produced in commercial quantities in 1902—antimony, arsenic, cobalt, corundum, flint and feldspar, fluorspar, graphite, infusorial earth, marble, mica, molybdenum, nickel, pyrites, quicksilver, serpentine, soapstone, tellurium, and tin.

Although no bismuth production was reported for 1902, the state supplied the entire United States output in 1901, amounting to 318.6 short tons, valued at $25,488. Of this, 253.6 tons came from Lake county and 65 tons from Ouray county. The bismuth contents varied from 4 to 12 per cent, and the ores also carried gold and silver values.[1]

The 964 operators reporting development work, distributed through the industries of gold and silver, bituminous coal, petroleum, asphaltum, iron ore, and manganese ore, gave employment during the year to 456 salaried officials, clerks, etc., who received $437,788 in salaries, and to 2,337 wage-earners, who were paid $2,340,058 in wages. They also paid $582,948 for work done by contract, which furnished employment to 911 employees. The miscellaneous expenses amounted to $213,816, and the cost of supplies and materials to $1,030,605.

The relative importance of the manufacturing industries closely allied to or based on the mining industry, using as their raw material the product of the mine or quarry, is shown in Table 2.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$102,830,137
Based upon products of mines or quarries:		
Chemicals and allied products	$1,306,845	
Clay, glass, and stone products	1,976,711	
Iron and steel and their products	10,365,780	
Metals and metal products, other than iron and steel	46,217,288	
Miscellaneous industries	6,046,255	
		65,912,879
All other		36,917,258

According to the above table, the value of the products of manufactures based primarily upon minerals mined and quarried amounted to $65,912,879, or 64.1 per cent of the total. The combined value of the product of mines and quarries in Colorado in 1902 and of

[1] Unites States Geological Survey, "Mineral Resources of the United States," 1901, page 259.

manufactures in 1900 was $143,433,423, of which manufactures constituted 71.7 per cent and the products of mines and quarries 28.3 per cent.

The average number of wage-earners in Colorado engaged in manufacturing, as reported at the Twelfth Census, was 24,725 and the wages paid them amounted to $15,146,667. In 1902 the average number of wage-earners reported as engaged in mining was 20,519 and the wages paid them amounted to $18,874,836. The two industries together, therefore, gave employment to an average of 45,244 wage-earners, and paid $34,021,503 in wages. Manufactures gave employment to 54.6 per cent of the wage-earners and paid 44.5 per cent of the wages, while mines and quarries furnished employment to 45.4 per cent of the wage-earners and paid 55.5 per cent of the wages.

Table 3, compiled from the reports of the United States Geological Survey, shows the value of the production of the principal minerals of the state, except copper ore for which values can not be obtained, from 1890 to 1902.

TABLE 3.—VALUE OF ANNUAL PRODUCTION OF PRINCIPAL MINERALS: 1890 TO 1902.

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Gold.[1]	Silver.[1]	Coal, bituminous.	Iron ore.	Petroleum.	Sandstones and quartzites.	Limestones and dolomites.	Siliceous crystalline rocks.
1890	$4,150,000	$24,307,070	$4,344,196	[2]	$280,240	$1,224,098	$138,091	$314,673
1891	4,600,000	27,358,384	4,800,000	[2]	559,005	750,000	90,000	300,000
1892	5,300,000	34,433,681	5,685,112	$587,903	692,160	550,000	100,000	100,000
1893	7,527,000	33,407,483	5,104,602	514,312	497,581	126,077	60,000	77,182
1894	10,616,463	30,704,375	3,516,340	676,141	303,652	69,105	132,170	49,302

[1] Estimates of the Director of the Mint for refined product—silver at coining values; the value in Table 1 is the value at the mine.
[2] Value not reported.
[3] Commercial value.
[4] Census figures, except for gold and silver.

Gold and silver.—Gold was discovered in 1852 near the mouth of Clear creek within the present boundaries of Arapahoe county by a Cherokee cattle trader, and in 1858 an expedition was organized to search for gold in the state. The passing of this expedition through Missouri and Kansas caused others to join the movement, and the reports of the discoveries that were carried back to "the states" spread like wildfire. The next spring and summer witnessed the great stampede for Pikes Peak and the Rockies. The first gold bearing lode was discovered May 6, 1859, in what is known as the Gregory mining district in Gilpin county.[1]

The mining growth of the state is best reviewed by considering the development of the more important of the gold and silver producing counties.

Boulder county is one of the pioneer counties of the state and has been the scene of active mining since its first settlement. The mining area is divided by somewhat indefinite boundaries into six mining districts, locally known as Grand Island (Caribou-Eldora), Sugar Loaf, Magnolia, Gold Hill, Central (Jamestown), and Ward. The county records show that the lode claim, placer claim, tunnel site, and mill site locations filed for record aggregate nearly 15,000. Of these, United States patents have been issued for about 1,000. Many of the location certificates filed are, of course, relocations of the same property. The ores are varied, including the common forms of iron and copper sulphide, chalcopyrite, and marcasite, while the complex silver and copper sulphides are not uncommon. The so-called telluride belt, extending from Magnolia to Ballarat, produces high-grade gold and silver telluride ores and is noted for its fine minerals.[2]

Chaffee county was formerly a part of Lake county, and the discovery of gold in the placer mines near Granite in the early days was almost coincident with the discovery of the placers of Clear Creek and Boulder counties. Great activity prevailed until 1862, when there was an exodus to other and supposedly better sections. The mining districts again became active during 1874–76. Since 1897 interest in the mines of this county has been gradually increasing, and the year 1902 marks not only more active operations but also a great increase in the list of new operators. The old placer mines near Granite have been operated with improved appliances. The leading districts are La Plata, Hope, and Red Mountain, in the northwestern part of the county; Dewey and Granite, in the northeastern; the Park Range region; the country adjacent to Turret, Whitehorn, Manoa, and Calumet; the Cleora district; and the Chalk Creek district. The county records show the filing of nearly 14,000 locations for placer and lode claims and mill sites and tunnel sites, and the issue of nearly 1,000 United States patents.[3]

[2] Report of the State Bureau of Mines, Colorado, 1901–2, pages 19 to 21.

[3] Ibid., pages 27 to 32.

Clear Creek county embraces the location of the first remunerative placer mine located in Colorado, discovered in 1859 near the mouth of Chicago creek. The county records show nearly 23,000 lode and placer claims and mill and tunnel sites, and the issue of about 1,300 United States patents. The county contains some of the most famous mining camps in the state—Idaho Springs, Silver Plume, Georgetown, and Empire. The underground development of some of the older mines has become quite extensive—the Dives-Pelicon, Bismarck, and 7–30 group near Silver Plume aggregating some 20 miles of underground workings.[1]

The mining history of Eagle county began with the year 1879, following the Leadville boom. The ores of the two regions are of a similar character. The county is rugged and contains within its confines the famous Mount of the Holy Cross. The mines are generally opened up by tunnels or inclines.[2]

Gilpin county, although the smallest in area, has always been one of the most important mining sections in the state. Beginning with 1859, mining has been continuous and its production large. Placer mining has been prosecuted each year since 1859–60, and the explorations of its lode mines have been carried even as deep as 2,200 feet. Central City, Black Hawk, Nevadaville, Eureka, and Gregory are some of its famous mining districts, the latter embracing Black Hawk and the Bates and Bobtail hills.[3]

Gunnison, one of the western slope counties, was the scene of a "rush" during 1880, second to none in the history of the state. Mining camps sprang up at numerous points, followed by smelting plants and mills.[4]

The first valid mineral locations were made in Hinsdale county in 1874. The ores of the district are, however, as a whole, of low grade and require concentration prior to shipment. The mineral resources are great and of a character to insure permanency of output.[5]

Lake county has been made famous by Leadville. Auriferous sand and gravel was the quest of the first gold seekers, and in 1860 a party of Gilpin county gold hunters crossed the range and discovered rich placers of California gold which produced several millions and were active for many years. It was not until the seventies that it was discovered that the heavy bowlders and dirt which had bothered the gulch miners were argentiferous lead carbonates. Leadville was settled in August, 1877, and at once became a heavy producer. The production of Lake county in 1902 was 47,357 fine ounces of gold, valued at $903,602, and 3,265,597 fine ounces of silver, valued at $1,659,210.

The history of Ouray county began practically with the year 1875, and was made famous at an early day by the rich copper-silver ores of the Yankee Girl, Guston, and other mines of the Red Mountain district. Later the publicity given to the Camp Bird mine of the Mt. Sneffles district added greatly to the reputation of the county and swelled the gold product of the state. This mine was discovered early in the eighties and was worked for a number of years to a limited extent on a pay streak near the foot wall, the operators being in ignorance of the immense values contained in an ore band near the hanging wall.

Pitkin, another of the leading mining counties, was traversed casually by early prospectors who made no discoveries of importance. But after experience gained at Leadville important discoveries were made in 1879 at Aspen, the most famous camp of the county. Owing to the inaccessibility to market, production was restricted until the Denver and Rio Grande Railroad reached Aspen in 1887.[6]

The veins of San Miguel county, which was established by legislative enactment in 1883, are similar to those of Ouray and San Juan counties. Gold and silver are generally associated with iron pyrite, chalcopyrite, lead sulphide, and zinc blende. Before the advent of railroad transportation in 1890, ores carrying high values were the only ones mined to any extent. At the present time the main production from this section is derived from ores having a gross value of from $8 to $20 per ton. Mining operations are conducted on a large scale, the largest producers being equipped with expensive milling plants.[7]

San Juan county is noted for the number and continuity of its fissure veins. Mining practically began in 1870, and was prosecuted with varying success until the railroad reached Silverton in 1882. It has since developed into one of the most important mining sections of the state. Nearly one-fifth of the area of the county is held under mineral locations.

Summit county was one of the original subdivisions out of which has been carved a number of counties. Its mining history begins with 1859. The placer beds on the Blue river and its tributaries are credited with a production of many million dollars' worth of gold. Ten Mile mining district is also in this county. The ore deposits occur both as fissure and as "contact" veins, the predominating value being silver, though nearly all the lode veins carry a small percentage of gold. The gold product, on the whole, exceeds the silver on account of the product of the placer mines.[8]

The Cripple Creek district, located in Teller county, is at present the most productive gold district in the United States, although the discovery of gold in that district was not made until February, 1891. The gold product of Teller county in 1902 was 699,487 fine ounces,

[8] Ibid., pages 213 to 220.

valued at $13,996,421. This was 52.6 per cent of the gold product of the state, and 18.9 per cent of the entire gold product of the country. The numerous mines are, with a few exceptions, developed by shafts, a number of which have passed the 1,000-foot mark.

Coal.—The lignite beds of the upper Missouri were noticed by Lewis and Clark, 1803–4; those of the Laramie plains by Fremont, 1842; and those of the Raton mountain region by General Emory as early as 1848. Coal was first developed at Boulder in 1860,[1] although the first production from the state was not reported until 1864. The Marshall mines of Boulder county had already been worked for some years, and the coal was bringing from $12 to $15 a ton in Denver.[2] In 1872 production was reported from Weld county, and in 1873 from Las Animas and Fremont counties.

Coal is now reported from 18 counties, the heaviest producers being Las Animas, Huerfano, Boulder, Fremont, Pitkin, and Gunnison counties, in the order named. These counties produced over 90 per cent of the coal reported for 1902.

The state is rich in the variety of its coals, which range from lignite to anthracite. Lignites are mined in Arapahoe, Boulder, Douglas, El Paso, Jefferson, Larimer, and Weld counties; bituminous in Garfield, Gunnison, Huerfano, Las Animas, La Plata, Mesa, and Pitkin counties; semibituminous in Fremont, Garfield, Gunnison, and La Plata counties; and anthracite in Gunnison county.[3] For statistical purposes the Bureau of the Census and the Geological Survey have classed the entire production of the state as bituminous.

Table 4, compiled from the reports of the United States Geological Survey, shows the production of coal in Colorado from 1864 to 1902, inclusive.

TABLE 4.—*Annual production of coal, bituminous: 1864 to 1902.*

1883	1,229,593		

Iron ore.—The first iron manufacturing enterprise was that of a small charcoal furnace at Langford, Boulder county, which was put in blast in 1864, with the object of supplying pig iron for foundry purposes. It went out of blast in 1865 and was soon afterwards abandoned. The ore was obtained in the neighborhood. The owners of this furnace built a foundry at Denver in 1861, but removed it to Black Hawk in Gilpin county in 1862. March 1, 1878, a rolling mill to reroll rails was put in operation at Pueblo, but it was removed to Denver during the year. On September 7, 1881, the first large coke furnace was put in blast at Pueblo, and the Bessemer steel works, of the same place, were finished in 1882.[4]

The iron ore production of the state in 1902 amounted to 306,572 long tons, valued at $1,084,424, an average of $3.54 a ton. This high average value of Colorado iron ore is due to its silver contents, and to its availability for use as a fluxing medium when mixed with other gold and silver ores in the smelter.

In the production of iron ore is included 13,275 tons of manganiferous iron ore, valued at $52,371, which was used in the manufacture of spiegeleisen at the steel works.

The following table, compiled from the reports of the United States Geological Survey, shows the production of iron ore in Colorado from 1889 to 1902:

TABLE 5.—*Annual production of iron ore: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Long tons.	YEAR.	Long tons.
1889	109,136	1896	215,819
1890	114,275	1897	187,314
1891	110,942	1898	318,480
1892	141,769	1899	307,557
1893	171,670	1900	407,084
1894	250,199	1901	404,037
1895	240,937	1902	306,572

Petroleum.—The first indications of petroleum were found about 1859 at Oil Springs in Fremont county, some 10 miles northwest of Florence. In March, 1862, crude oil was collected from the springs by sinking shallow wells, and between 1862 and 1865 the oil collected was refined and most of it was transported by team to Pueblo, Denver, and Santa Fe. For some of this refined oil as high as $5 a gallon was realized. The advent of railroads rendered the industry unremunerative and it was abandoned. In 1881, while drilling a well for water near the coal mines at the town of Coal Creek, the drillers discovered oil at a depth of 1,260 feet. The discovery was followed up with varying success, no production being reported until 1887.[5]

The development of the Boulder field was begun near the close of 1901, and there was great activity throughout the state in 1902. The superior quality of the petroleum developed at Boulder led to a large amount of drilling in northern Colorado. Operations were active at Boulder, Fort Collins, and in the Florence field and to a lesser extent in Pueblo, Archuleta, Rio

Blanco, and Routt counties and at Raton. The production of the Boulder pool in 1902 amounted to 11,800 barrels. It will be seen from Table 6 that the largest production, 824,000 barrels, was made in 1892, the average production since being but a little more than half that amount.

Table 6, compiled from the reports of the United States Geological Survey, shows the annual production of crude oil in Colorado from 1887 to 1902, inclusive.

TABLE 6.—*Annual production of petroleum: 1887 to 1902.*

1893	594,390	1902	396,901

Sandstones and quartzites.—The state contains a variety of sandstones, which are now quite generally quarried. Reports for 1902 showed 51 quarries and 47 operators, distributed among Boulder, Delta, Douglas, Eagle, El Paso, Fremont, La Plata, Larimer, Las Animas, and Pueblo counties, the largest number being in Boulder county. The Red Beds yield building stones of a great variety of shades, texture, and strength. Numerous quarries, which furnish fine yellow and blue-gray stone, have been opened in Boulder county on the Cretaceous sandstones. In Fremont county there occurs a fine grayish or buff stone of Laramie age that closely resembles the Subcarboniferous stone of Berea, Ohio.[1]

Limestones and dolomites.—Limestone is quarried in 8 counties—Chaffee, El Paso, Fremont, Gunnison, Jefferson, La Plata, Pitkin, and Pueblo. A little more than three-fourths of the product is used for flux.

Copper.—The production of copper ore from mines operated for that mineral is comparatively small, the value of the product so reported being but $71,411 from 18 mines. There is, however, a large copper production by the smelters of the state, who purchase argentiferous copper ores and mattes in the open market.

Clay.—The clay sold by the miner, which is the only clay reported, is but a small part of the actual clay product of the state. It should be borne in mind that the clay which is manufactured by the producers was not taken into account in this inquiry. Clay valued at $67,434 was mined and sold as such by four establishments. The total value of brick and tile, and pottery, terra cotta, and fire clay products produced in the state in 1899 was $1,071,388. In 1900 the value of the same class of clay products was $1,200,519, and in 1901 it was $1,594,867, the state then ranking fourteenth in the value of these products. In 1902 the state ranked twelfth, though the value of the clay products had increased to $2,200,983.

Siliceous crystalline rocks.—Ten quarries of siliceous crystalline rocks were in operation in the counties of Boulder, Chaffee, Clear Creek, Fremont, Jefferson, Gunnison, and Larimer, and produced stone valued at $66,023—chiefly building stone. Fine gray granite occurs at Georgetown and Lawson, in Clear Creek county, and there are inexhaustible quantities of good material all through the mountains.[2]

Uranium and vanadium.—The only production of these metals in the United States was from three mines in Colorado—one each in Gilpin, Montrose, and San Miguel counties. The output amounted to 3,810 short tons of ore, valued at $48,125, the bulk of this production being contributed by the San Miguel county mine. The production of uranium in 1900 was reported as 153 short tons, carrying from 5 to 16 per cent of uranium oxide, and in 1901 it was 375 short tons.[3]

Lead and zinc.—The lead and zinc production in Colorado is practically all from the smelting of ores carrying precious metals. The nonargentiferous lead and zinc ore mined in 1902 amounted to only 1,636 short tons, of which 1,536 tons were zinc.

All other minerals.—The first production of Portland cement was reported for 1901 from one establishment in Fremont county. In 1902 two establishments were in operation; one of these quarried its raw material. As the other manufactured from purchased material, the statistics of its operation are not included in the report on mines and quarries.

Gypsum has been quarried to a small extent for a number of years, the bulk of the product being calcined into plaster of Paris. Numerous deposits of gypsum are known to exist in all the Rocky mountain territory. At the census of 1890 the beds that had so far been worked were in the neighborhood of Big Thompson, Larimer county, and Colorado Springs, El Paso county. Production of plaster of Paris was reported from the mill at Colorado Springs as early as 1879, when the output was 150 short tons. The production of 1902 was from one establishment near Loveland, Larimer county.

The natural gas produced in Colorado comes from the oil wells. In 1902 the output was valued at $1,900.

The precious stones reported for 1902 were smoky quartz and amazon stone. Smoky quartz occurs at and near Pikes Peak, where it is abundant in a coarse granite, associated with amazon stones—crystals of green feldspar—for which that locality is famous. It is also found at Mt. Antero, Chaffee county. One of

[2] Stones for Building and Decoration, page 53.

[3] United States Geological Survey, "Mineral Resources of the United States," 1900, page 265, and 1901, page 270.

the finest faceted stones in the world, measuring 3½ inches in length, exhibited at the Columbian Exposition, was from Mt. Antero. Aquamarines have also been found at Mt. Antero within recent years. Topazes have been found at Cheyenne mountain, Pikes Peak, and at Nathrop. Some fine rock crystal has been furnished by the state, especially from Mt. Antero. Amethyst has been reported from Cripple Creek and from localities in Park and Mineral counties. Turquoise is reported from the southern part of the state, and prosopite, a fluoride of alumina, occurs at Pikes Peak.

Tungsten ores, wolframite, and hubnerite have been found in quantity in San Juan, Boulder, Gilpin, Ouray, and Lake counties. In 1902 production was reported from three mines—two in Boulder county and one in San Juan. The only other producer in the United States was one mine in Connecticut. It is only within a few years that it has been known to exist in commercial quantities in Colorado. Shipments were reported in 1900 of 45½ short tons, carrying from 60 to 71 per cent of titanic acid.[1]

[1] United States Geological Survey, "Mineral Resources of the United States," 1900, page 258.

CONNECTICUT.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Connecticut for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Siliceous crystalline rocks.	Limestones and dolomites.	Sandstones and quartzites.	Feldspar.	Crystalline quartz.	Flint.	All other minerals.[1]
Number of mines or quarries	90	49	12	7	6	4	4	8
Number of operators	78	44	7	7	6	3	4	7
Salaried officials, clerks, etc.:								
Number	151	87	18	15	8	8	2	13
Salaries	$132,095	$75,682	$18,830	$13,554	$5,345	$6,030	$1,200	$11,454
Wage-earners:								
Average number	1,497	943	135	142	71	18	10	178
Wages	$808,772	$635,334	$66,765	$73,939	$33,672	$8,792	$4,835	$85,435
Miscellaneous expenses	$59,918	$31,859	$9,028	$6,881	$4,564	$1,450	$675	$5,461
Cost of supplies and materials	$236,075	$118,231	$64,346	$14,668	$10,677	$700	$1,965	$25,488
Value of product	$1,425,959	$812,141	$205,371	$128,579	$73,764	$32,075	$11,575	$162,454

[1] Includes operators as follows: Asbestos, 1; clay, 1; garnet, 2; iron ore, 1 (2 mines); marble, 1; and tungsten, 1.

The state ranked fortieth in mining in 1902 according to the value of its product. Its principal mineral products were nonmetallic. Connecticut, in early years, was a pioneer in mining enterprise, but later its mines, never very productive, have fallen largely into disuse. The first of the early colonists to turn his attention in the direction of mining seems to have been Governor Winthrop, who, from 1650 to 1660, engaged at intervals in examining the metalliferous indications of the Connecticut valley, in the vicinity of Haddam and Middletown. There is no reason to suppose that any actual mining was ever executed by him.[1]

The copper mines of Simsbury were discovered about 1705,[2] ruined a number of successive proprietors, and were finally made into a state prison, long since abandoned. In 1709 the first mining company organized in the United States was chartered to operate these mines. The material for the "Granby coppers," coined in 1737, and for other coins, including the first United States coinage, was obtained from Simsbury.[3] The finding of ore in this locality prompted the discovery of the Schuyler mine in New Jersey in 1719. A cobalt mine in Chatham was worked in 1762, and about the same time the Southampton lead mine was opened, but neither of these enterprises met with much success. In 1836 copper was extensively mined at Bristol, the workings being at this time among the most important in the United States. The Ore Hill iron mine of Salisbury in 1849 supplied 16 furnaces in Litchfield county with a fibrous and massive hematite, which furnished forge pig of the finest quality.[4] The most important silver-lead mine in the state was near Middletown. It was opened in 1852, although previously operated to some extent probably many years prior to the Revolutionary War.[5]

Minerals occurring in Connecticut but not reported in commercial quantities during 1902 are numerous. Barytes was mined in New Haven county as early as 1870, but none has since been reported. Bismuth is disseminated in small quantities through the quartz of Fairfield county. Bornite, green carbonate of copper, vitreous copper, copper pyrite, and native copper occur chiefly in Hartford, Litchfield, and New Haven counties. Emery and corundum are found near Litchfield,[6] graphite or plumbago is disseminated through rock in the same county, and glass sand occurs on the shores of Lake Quassapaug. Copper occurs in many forms throughout the state. A number of contact deposits in sandstone at junctures with gneiss were formerly worked, especially at Bristol.[7] Large deposits of infusorial earth and tripoli occur, but no production was reported for 1902. Indications of galena are abundant[8] throughout the state, but there are few localities where lead mining has been carried on to any

[1] Metallic Wealth of the United States, by J. D. Whitney, page xxii.

[7] Ore Deposits of the United States, by James F. Kemp, page 158.
[8] Metallic Wealth of the United States, page 392.

extent. Manganese ore in small quantities is frequently found in connection with the iron ores of the Salisbury district.[1] Efforts have been made to locate this ore in sufficient quantities to pay for its separation from iron, but they have thus far proved futile. Mica is found near Branchville and New Milford, and molybdenum at Haddam in the gneiss quarries. Niccolite occurs in Middlesex and Fairfield counties, associated with smaltite or gray cobalt ore, which is disseminated in mica slate accompanied by galenite and sphalerite.

Precious stones—agate, beryl, and topaz—have been reported as found in the state. Pyrites, pyrrhotite, and chalcopyrite occur in various localities. Rutile occurs in Hartford, Litchfield, and Fairfield counties. Some silver is generally found in the galena of the Eastern states,[2] but the ores have never yet proved abundant enough to be important. Talc occurs with slate in gneiss near Bristol, Hartford county, and a silicate of zinc is found, in Fairfield county, in white limestone with galena and blende.[3]

The following table shows the value of the manufactured products of the state in 1900 based primarily upon the products of mining and quarrying in comparison with the total for all manufactures reported:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$352,824,106
Based upon products of mines or quarries:		
Chemicals and allied products	$852,860	
Clay, glass, and stone products	3,167,010	
Iron and steel and their products	61,079,340	
Metals and metal products, other than iron and steel	78,826,528	
Miscellaneous industries	14,445,102	
		158,370,840
All other		194,453,266

As shown in the above table, the product of mines and quarries was used as material in the manufacture of 44.9 per cent in value of the manufactures of Connecticut. Most of this mineral product was obtained from other states.

The value of the manufactured product reported for 1900 was $352,824,106, while the value of the product of mines and quarries in 1902 was $1,425,959. From these figures it will be seen that the production of mines and quarries represents only four-tenths of 1 per cent of the total value for the combined industries, and manufactures, 99.6 per cent. The manufacturing industries as reported in 1900 gave employment to 176,694 wage-earners who were paid $82,767,725 in wages; in 1902 there were employed at the mines and quarries 1,497 wage-earners who received $808,772 in wages. Of the combined totals, mines and quarries gave employment to eight-tenths of 1 per cent of the wage-earners and paid 1 per cent of the wages, while manufactures employed 99.2 per cent of the wage-earners and paid 99 per cent of the wages.

The following table, compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals of the state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Siliceous crystalline rocks.	Limestones and dolomites.	Sandstones and quartzites.	Feldspar.
1890	$1,061,202	$131,697	$920,061	(1)
1891	1,167,000	100,000	750,000	(1)
1892	700,000	95,000	650,000	(1)
1893	652,459	155,000	570,346	(1)
1894	504,390	204,414	322,934	(1)
1895	779,361	154,333	397,853	(1)
1896	794,325	138,945	426,029	$5,050
1897	616,215	178,410	364,604	24,875
1898	682,768	142,057	215,733	[2]12,020

1901	616,654	140,424	146,814	54,858
1902[3]	812,141	205,371	128,579	73,764

[1] Not reported.
[2] Includes value produced in New York in 1898 and 1900, and Maine in 1898.
[3] Census figures.

The principal mineral production in Connecticut is from quarries, siliceous crystalline rocks leading, although this industry has materially decreased since 1891. The production of sandstones and quartzites has also fallen off largely, but the production of limestones and dolomites increased from $131,697, in 1890, to $205,371, in 1902, or 55.9 per cent.

Siliceous crystalline rocks.—The production of siliceous crystalline rocks in 1902 was valued at $812,141. Of this amount, 43.2 per cent was stone sold in the rough or dressed for building purposes and 36.3 per cent was crushed rock for roads, railroad ballast, and concrete; the remainder being dressed for monumental purposes, made into paving blocks, or prepared for use as curbing, flagging, riprap, rubble, etc.

Extensive deposits of granite are found throughout the New England states, the Connecticut product being usually distinguished from other granites by a fine grain and light gray color.[4] The most important quarries in Connecticut are found bordering on Long Island sound, although a production was reported during 1902 in every county except Tolland.

At Millstone, New London county, is a quarry from which millstones were quarried for use in old-fashioned windmills a century and a half ago. The stone is rather dark colored and is now used chiefly for building, monumental work, and for paving blocks. Monumental stone is quarried only at Groton, the granite being fine grained, hard, and well adapted to this use. The Waterford granite is a fine grained biotite, gray in color,

[4] Tenth Census, Special Report on Building Stones, Vol. X, page 129.

and suitable for both monumental and building purposes. A considerable production was reported in 1902. A gray stone is also quarried near Oneco in Windham county.

At Leetes Island, New Haven county, a feldspathic pink gneiss, excellent for heavy construction and bridge work, is quarried. This stone was used in the foundation of the Bartholdi Statue of Liberty in New York harbor. The Stony Creek quarries produced large quantities of red granite, which was used chiefly for building purposes. The red or pink color of this stone is most attractive. At Ansonia and numerous other points there are quarries of more or less importance. There is a large quarry at Sachem Head, which, however, did not report any production during 1902.[1]

Limestones and dolomites.—The production of limestone during 1902 was valued at $205,371, an increase of 46.3 per cent over the production reported for 1901. All the Connecticut limestones are crystalline in texture[2] and comparatively free from admixture of clay or magnesia, and are therefore well adapted for burning into lime, for which purpose, except a very small amount reported as flux, the production of 1902 was wholly used. That limestones are not used in this state for roadmaking material is accounted for by the abundance of the harder and more permanent granitic rocks.

Sandstones and quartzites.—Third in importance among the mineral industries of Connecticut is the quarrying of sandstone, the value of the product for 1902 being $128,579. The quarries are found principally adjacent to the Connecticut river, at Portland, Middlesex county. A small production is also reported from Hartford and New Haven counties. This stone is sold chiefly in the rough and used for building purposes. It quarries easily, works well,[3] and possesses a very rich color, but sometimes does not weather well in the changeable climate of northern United States.

Feldspar.—Connecticut, in 1902, produced in value 29.5 per cent of the feldspar reported for the United States. It was quarried in Fairfield, Hartford, Litchfield, and Middlesex counties. It is obtained from pegmatitic dikes[4] occurring in gneisses and schists and is chiefly orthoclase. In some localities there are large masses of nearly pure spar, but generally the occurrence is an intergrowth of quartz and feldspar. The associated minerals are tourmaline, garnet, and beryl.

Crystalline quartz.—The crystalline quartz quarried during 1902 amounted to 10,400 short tons, and was valued at $32,075, or about three-fourths of the value reported for the entire United States. The mines are situated at New Milford, Roxbury, and Washington in Litchfield county, and at Southbury, New Haven county. Crystalline quartz is used in wood finishing, to prepare the surface of the wood for polishing, and in the stone cutting trade,[5] especially by the marble men, as an abrasive. It is also crushed and sized for use in the manufacture of sandpaper or pulverized for sale as tripoli.

Flint.—The flint production of Connecticut during 1902 was reported as 852 short tons of crude, valued at $1,775, and 960 short tons of ground, valued at $9,800, a total valuation of $11,575, which is somewhat less than was reported in 1901. The quarries are all located in Fairfield and Litchfield counties.

All other minerals.—A considerable amount of marble was quarried near East Canaan, Litchfield county, during 1902, and it was all used for building purposes. Deposits of serpentine[6] and verd antique marble occur in the vicinity of New Haven, but no quarrying was reported.

Iron ore of importance is mined in the extreme northwest corner of the state, near Salisbury, Litchfield county.[7] The ores are similar to those of Massachusetts. Statistics of the production, which is small, have been for some years consolidated with the production of other New England states and can not be shown separately for 1902 without disclosing the business of the only operator engaged in the mining. The Salisbury mines, two in number, are among the oldest in the country, and have been famous for the quality of their ore and the uses to which the iron made from it has been put.

One kaolin mine was reported in Litchfield county, statistics for which are included under "all other minerals" to avoid the disclosure of individual operations. In Litchfield county, in the vicinity of Roxbury, are also located 2 garnet quarries. A large portion of the product is used in the manufacture of sandpaper.

More than one-fifth of the entire asbestos production of the United States is mined in Litchfield county. During 1902 the asbestos produced in this state was chiefly in the crude form. Crushing the ore and separating it by sifting are the only processes thus far undertaken at the mine.

A small quantity of scheelite, which when refined assays about 79 per cent tungstic acid, was mined during 1902, near Longhill, Fairfield county. It occurs in a quartz vein between an amphibole gneiss and a bed of crystalline limestone.[8]

DELAWARE.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Delaware for 1902.

TABLE 1.—*Summary: 1902.*

	Total.	Siliceous crystalline rocks.	Clay.
Number of mines or quarries	12	6	6
Number of operators	12	6	6
Salaried officials, clerks, etc.:			
Number	29	16	13
Salaries	$28,047	$15,307	$12,740
Wage-earners:			
Average number	504	335	169
Wages	$222,622	$153,150	$69,472
Miscellaneous expenses	$39,278	$19,688	$19,590
Cost of supplies and materials	$45,361	$18,126	$27,235
Value of product	$448,467	$276,753	$171,714

The mineral wealth of the state consists chiefly of its deposits of granitic building stones, which have been extensively quarried, and clay deposits, which were among the first in the country to be developed on a commercial scale. While the state was not a producer in 1902 of feldspar, bog iron ore, greensand marl, limestone, and "blue rock," these minerals occur at various points and were mined in former years. Among the minerals occurring in the state which, as yet, have received little or no attention by miners are: Asbestos, amber, and serpentine.[1]

Certain manufacturing industries are closely allied to or are based on the mining industry, using as their raw material the product of the mine or quarry. The relative importance of these branches of manufacture, as indicated by the value of their products, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$45,387,630
Based upon products of mines or quarries:		
Iron and steel and their products	$9,233,012	
Clay, glass, and stone products	723,775	
Metals and metal products, other than iron and steel	275,367	
Chemicals and allied products	883,558	
Miscellaneous industries	1,509,955	
		12,625,667
All other		32,761,963

[1] United States Geological Survey, "Mineral Resources of the United States," 1887, page 718.

The total value of the products of the manufacturing industries, based on the products of mining, was, as shown by Table 2, $12,625,667, or 27.8 per cent of the total value of the product of all manufacturing industries in the state in 1900. During the same year there were employed in all branches of manufacture in the state 22,203 wage-earners, who were paid $9,259,661 in wages. In 1902 the mines and quarries of the state gave employment to 504 wage-earners, who received $222,622 in wages. Manufactures, therefore, gave employment to 97.8 per cent of the wage-earners and paid 97.7 per cent of the wages; mining employed 2.2 per cent of the wage-earners and paid 2.3 per cent of the wages.

Table 3 shows the annual production of siliceous crystalline rocks and clay.

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Siliceous crystalline rocks.	Clay.
1890	$211,194	(1)
1891	210,000	(1)
1892	250,000	(1)
1893	215,964	(1)
1894	173,805	(1)
1895	73,138	(1)
1896	67,775	(1)
1897	272,469	$99,441
1898	677,754	82,286
1899	1,039,349	71,742
1900	608,028	102,005
1901	671,204	112,883
1902[2]	276,753	171,714

[1] Not reported separately. [2] Census figures.

Siliceous crystalline rocks.—The granitic deposits of the state are confined, in the main, to a comparatively small belt or area adjacent to the city of Wilmington.[2] The rock is of a dark gray gneissoid character and has been used to a limited extent for building purposes, but has been more largely used in coarser construction work and in roadmaking.[3] This rock has been quarried for many years.

[2] The New International Encyclopedia, Vol. V, page 768.

[3] Stones for Building and Decoration, by George P. Merrill, page 55.

Clay.—The clays of Delaware constitute the major part of its mineral wealth. A large proportion of the workable deposits, comprising clays suitable for brick and terra cotta making and for china clay, occur in Newcastle county.[1] The clay product of chief importance, however, and that in the production of which the state holds a conspicuous place, is kaolin. The beginning of the industry of kaolin mining in Delaware is approximately coincident with that of the same industry just over the line in Pennsylvania, where it began in 1839.[2] For many years the kaolin deposits of these two states made up the total output of the country. While kaolin of excellent quality and of extensive occurrence has been mined at many different places, the present center of the industry of kaolin or china clay mining is in the vicinity of Hockessin, in Newcastle county. The industry of mining is supplemented in Delaware by the conversion of the raw kaolin into china clay, and the bulk of the state's product of this mineral is shipped in this form.

FLORIDA.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Florida for 1902.

TABLE 1.—*Summary: 1902.*

	Total.	Phosphate rock.	Limestones and dolomites.	All other minerals.[1]
Number of mines or quarries	71	61	6	4
Number of operators	46	36	6	4
Salaried officials, clerks, etc.:				
Number	218	192	3	23
Salaries	$228,868	$206,108	$2,410	$20,350
Wage-earners:				
Average number	3,146	2,866	87	193
Wages	$1,082,030	$996,801	$28,054	$57,175
Contract work	$4,021			$4,021
Miscellaneous expenses	$304,142	$283,149	$2,208	$18,785
Cost of supplies and materials	$618,057	$542,322	$14,769	$60,966
Value of product	$2,943,806	$2,655,463	$63,571	$224,772

[1] Includes operators as follows: Clay, 2; fuller's earth, 2.

The state ranked thirty-fifth in 1902 in the value of products of mines and quarries, with a total of $2,943,806. The mining industry in the state is confined to nonmetallic minerals. Chief among these, both in extent and development, is phosphate rock. Also, in a relative sense, the state's product of fuller's earth is of importance and its wealth in clay deposits is worthy of note.

Other minerals found in the state but not commercially produced in 1902 are: Gypsum, a rather extensive bed of which has recently been discovered near Panasoffkee;[1] lignite or brown coal, deposits of which occur on the Suwanee river, and at one time were worked for fuel;[2] and hydraulic cement rock, of which a large deposit occurs near River Junction, extending for several miles along the left bank of the Apalachicola river southerly to Aspalaga, and comprising over 2,000 acres, with a thickness of at least 80 feet. Enough has been exposed to indicate that the deposit contains sufficient raw material to produce over two billion barrels of cement. The raw material is white, and the manufactured product is as white as the whitest marble.[3]

Development work in the state in 1902 was confined to phosphate rock, clay, and petroleum, cost $25,314, and was of interest chiefly because of the borings and testings made in Sumter county for petroleum.

[1] United States Geological Survey, Twentieth Annual Report, 1898–99, Part VI, page 662.
[2] Ibid., "Mineral Resources of the United States," 1882, page 675.
[3] Ibid., Twentieth Annual Report, 1898–99, Part VI, page 549 ff.

Certain manufacturing industries use as their raw material the product of the mine or quarry, and their relative importance, as indicated by value of products, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$36,810,243
Based upon products of mines or quarries:		
Chemicals and allied products	$500,239	
Clay, glass, and stone products	229,447	
Iron and steel and their products	320,507	
Metals and metal products, other than iron and steel	125,458	
Miscellaneous industries	981,715	
		2,157,366
All other		34,652,877

The total value of the products of manufacturing industries based on mining was, as shown by Table 2, $2,157,366, or 5.9 per cent of the total value of the products of all manufacturing industries in the state in 1900. During the same year there were employed in all branches of manufactures 34,230 wage-earners, who were paid $10,683,038 in wages. In 1902 the mines and quarries gave employment to 3,146 wage-earners, who received $1,082,030 in wages. Manufactures, therefore, employed 91.6 per cent of the wage-earners of the two industries and paid 90.8 per cent of the wages, while the mining industries employed 8.4 per cent of the wage-earners and paid 9.2 per cent of the wages.

In Table 3 is shown the value of the annual production, as compiled from the reports of the United States Geological Survey, of the principal minerals of the state from 1889 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Phosphate rock.	Limestone.	YEAR.	Phosphate rock.	Limestone.
1889	$32,800	(1)	1896	$1,547,353	$16,982
1890	338,190	(1)	1897	1,493,515	18,889
1891	703,013	(2)	1898	1,847,796	91,330
1892	1,418,418	(2)	1899	2,804,061	44,002
1893	1,979,056	$35,000	1900	2,983,312	128,381
1894	1,666,813	30,639	1901	3,159,473	51,870
1895	2,112,902	10,550	1902[3]	2,655,463	63,571

[1] Not reported separately. [2] No production. [3] Census figures.

Phosphate rock.—This mineral, which constitutes the state's most valuable resource, occurs principally in a belt extending from Lake Okechobee on the south to the vicinity of Tallahassee on the north,[1] approximating 240 miles in length and averaging about 30 miles in width. Deposits of commercial value are not continuous throughout this large area, but are widely scattered. Four classes of phosphate rock have been produced. These, in the order of total values of product for the years 1888 to 1902, are: Hard rock, land pebble, river pebble, and soft rock.

The following table shows the product of phosphate rock by classes since its mining began in 1888:

TABLE 4.—*Annual production of phosphate rock by kinds: 1888 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	PRODUCTION (LONG TONS).				
	Total.	Hard rock.	Soft rock.	Land pebble.	River pebble.

1902	785,430	429,384	.....	350,991	5,055

[1] Included with hard rock.

Nodular amorphous phosphatic deposits in the state were found widely distributed many years ago. It was not believed at that time, however, that they were of sufficient importance either in quantity or quality to warrant their exploitation.[2] The industry of phosphate mining, which brought the state into world prominence, followed close upon the discovery in 1886,[3] on the Peace river, of phosphate rock of apparently high grade. By 1888[2] tentative operations were under way on this river and they met with such marked encouragement that many who had hitherto remained skeptically watching developments came into the field and the year 1889 saw two companies dredging the river bottom with modern and expensive equipment.[2] Thus the industry began in the state with the mining of river pebble.

At the close of 1888 Mr. Albert Vogt, living near Dunnellon, a village on the Withlacoochee river in Marion county, found fossil sharks' teeth in a white subsoil. Some of this white subsoil, being submitted to a chemist for analysis, was found to contain a large percentage of phosphate of lime. This deposit extended in a more or less "pockety" belt over a considerable district. Active explorations were begun and the known area of beds was rapidly enlarged.[3]

The mining of river pebble grew rapidly from the first, and when, in 1891, the period of speculation and development of the land deposits began to give way to the systematic production of this rock, the industry immediately took first rank. By the end of this year 215 companies had been formed to work the deposits, and the number was constantly increasing.[4]

In 1892 the state succeeded in tripling, as compared with the preceding year, its exports of phosphate rock, compelled consumers to acknowledge the industrial value of the product, and forced the majority of foreign producers from the field.[5] In 1894 the state, by exceeding the production of South Carolina, became the chief producer of phosphate rock in the world, with a product of 527,633 long tons; it has occupied this position ever since.

The hard rock phosphate is white or creamy, and varies in texture and structure. It is mined over a belt reaching from the vicinity of Bay City on the south to the vicinity of Albion on the north, and having an average width of about 10 miles with an area of about 900 square miles.

Land pebble is found in a number of localities in the peninsular portion of the state, the center of production being in Polk county. Between the Peace river and the Gulf its occurrence is general beneath a large part of the surface, and it is also found in varying quantities in many other places. It is essentially a mass of white phosphatic pebbles lying in a matrix of phosphatic clay or sand, usually of the two in combination. The matrix is easily disintegrated by water and the pebbles are washed out by appropriate machinery. The pebbles vary in size from grains to stones 1 inch in diameter, the average size being from one-quarter to one-half inch.

River pebble is found in bars in the rivers of southern Florida, the bulk of the production of this class of rock having been taken from the Peace river. Other rivers carrying the pebble are the Alafia, the two Manatees, and the Caloosahatchee. It has also been found in many other streams entering the Gulf and in Black creek, a tributary of the St. Johns. With these pebbles, the remains of vertebrate animals are often found. In color, the river pebbles are blue or black and in size they vary from 1 inch in diameter down to grains, usually finer as distance down the stream is gained.[6]

The soft rock phosphate occurs both as a deposit by itself and in deposits of hard rock, filling the spaces

between the bowlders. It may be either clayey or sandy in its nature.[1]

Limestones and dolomites.—The production of limestone in the state has been limited to the last few years and the aggregate output is not large. It is divided about equally in use between building stone, paving, roadmaking, and jetties, and for burning into lime.[2] Limestone is the underlying rock throughout the state,[3] and its outcroppings in Dade, Washington, and Marion counties were the principal points of production in 1902.

All other minerals.—Clay mining in 1902 was confined to the two counties Lake and Putnam, although many valuable clay deposits have been found at various places in the state. Kaolin beds of superior quality occur in Citrus, Lee, and Hernando counties. In the vicinity of Okahumpka some fine specimens have been found of a clear, white quality, comparing favorably with the kaolin used in New Jersey in the manufacture of porcelain ware. At Bluffsprings, in Escambia county, occurs a bed of potters' clay from which a good quality of sewer pipe can be made.[4]

The great sedimentary kaolin deposits in the vicinity of Villa City, Lake county, on the Palalakaha creek, half way between St. Augustine and Tampa, are remarkably alike for their extent and quality. Prospecting has shown the clay to be some 30 feet in thickness and similar chemically to that of Limoges.[5] What are said to be the purest ball clays found in the United States occur at Edgar, near Leesburg.[6]

Fuller's earth includes a number of clay-like substances having strong absorbent qualities.[7] It is found in many shades of color varying from gray to dark green, turning to white on drying; some varieties are kaolinite and others are smectite.[8] For many years it was employed only as a detergent in fulling cloth, but with the increased production of cottonseed oil, it came to be used for clarifying such oil and also for clarifying lard oil and petroleum.[9] The utility of fuller's earth for this purpose was discovered in the United States.[10] For some years the supply had been drawn principally from England, but the new demand stimulated the search for commercial deposits in this country. In 1893, quite by accident, the first discovery of this useful earth in the United States occurred near Quincy, Fla. An effort to burn brick from a bed of clay failed, the material exfoliating instead of forming a coherent mass. An Alsatian cigarmaker called attention to the close resemblance of this peculiar clay to the German fuller's earth.[9] Investigation followed and the deposit proved to be fuller's earth of a very high grade. Since its discovery practically the entire output in the United States has come from this state. In addition to the deposits in the vicinity of Quincy, others have been found at Mt. Pleasant, Norway, River Junction, Ballards point, near Tampa, and at other points.[11] In 1897 a peculiar chocolate-brown earth was discovered near Ocala, which is claimed to be superior to all other American and to all English fuller's earths as a filtering and clarifying agent for oils.[12]

GEORGIA.

Table 1 is a summary of the statistics for the productive mines and quarries of the state of Georgia for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Siliceous crystalline rocks.	Marble.	Coal, bituminous.	Iron ore.	Gold and silver.	Limestones and dolomites.	Bauxite.	All other minerals.[1]
Number of mines or quarries	149	26	5	3	19	45	8	16	27
Number of operators	127	24	5	2	13	45	8	3	27
Salaried officials, clerks, etc.:									
Number	304	45	24	24	60	59	15	23	54
Salaries	$209,281	$34,536	$23,050	$20,326	$42,361	$29,508	$6,752	$19,355	$33,393
Wage-earners:									
Average number	2,820	724	310	168	688	334	152	93	351
Total wages	$1,085,047	$382,559	$105,709	$74,649	$229,138	$107,718	$42,516	$36,559	$106,199
Contract work	$122,619			$121,464		$1,030		$125	
Miscellaneous expenses	$231,145	$32,588	$68,557	$18,319	$76,622	$9,684	$3,348	$9,564	$12,463
Cost of supplies and materials	$566,067	$188,278	$77,205	$107,994	$64,932	$33,123	$17,905	$23,917	$52,713
Value of product	$3,117,358	$803,778	$660,517	$589,018	$462,717	$149,150	$111,589	$96,194	$254,395

[1] Includes operators as follows: Asbestos, 1; cement, 2; clay, 7; graphite, 2; infusorial earth, tripoli, and pumice (operator reported under talc and soapstone); manganese ore, 6; mica, 1; mineral pigments, crude, 4; sandstones and quartzites, 1; slate, 1; sulphur and pyrite, 1; talc and soapstone, 1.

The state ranked thirty-fourth in 1902 in the value of products of mines and quarries, with a total of $3,117,358. The scope of this branch of industry in the state is quite broad, nineteen different minerals contributing to the total. Gold and silver, in the production of which in former years the state was conspicuous, are still important products, though not commensurate with the abundant deposits of these metals. In recent years the state's most important mineral products have been granite and marble; the quality of the deposits of both these minerals is high and their quantity practically unlimited. From the bauxite deposits of the state more than three-fourths of the total output of the United States is drawn. The extensive occurrence of limestone, iron ore, and slate also add materially to the state's mineral wealth and promise much for future industrial activity.

In addition to the nineteen minerals produced commercially in 1902, the occurrence of many others has been definitely established. Some of these have been exploited to a limited extent, while with others development work has not passed beyond the incipient stage and still others remain untouched. Among the more important of these is copper ore, which before the Civil War was successfully mined in Fannin and Cherokee counties. Large quantities of high-grade ore have been taken from the mines of these counties and the deposits are undoubtedly of considerable economic importance. Copper ore deposits have also been discovered in Fulton, Paulding, Lumpkin, Haralson, Lincoln, and other counties in the northern part of the state. The most important form of the ore is the copper pyrites.[1]

Extensive deposits of corundum occur in many sections of northern Georgia, but chiefly in Rabun county on Laurel creek, where the first discovery of this mineral in the state occurred in 1871. Between 1880 and 1893 the deposits of this county, together with a deposit at Trackrock, in Union county, were extensively worked; their product was one of the main factors in the corundum trade of the country for abrasive purposes. The low prices prevailing for this mineral during the last few years are chiefly responsible for the mines remaining inactive. Corundum has also been found in Habersham and other counties.[2]

Of the precious stones, amethysts of good quality have been found in Rabun county; rubies and sapphires of small size have been obtained in connection with corundum mining, and green beryl, suitable for cutting, has also been found. Some good moonstones have been cut from the feldspar of Upson county.[3] Several diamonds have been found in Hall county, ranging in value up to $200.[4] Others have been found in Lumpkin, White, and Dawson counties.[5] Opal occurs in some of the clay beds of Washington and Bulloch counties.[5]

Serpentine, one of the most beautiful working stones

[1] Georgia, Historical and Industrial, page 140.
[2] Ibid., page 133.
[3] Ibid., page 66.
[4] Statistics of Georgia, by George White, page 307.
[5] The Commonwealth of Georgia, by J. T. Henderson, page 140.

of the state, occurs in commercial quantities in Cherokee county near Holly Springs, where it has been quarried to a limited extent. The stone is of a dark green color, mottled and streaked with white and black, admits of an excellent polish, and is very highly prized for ornamental purposes.[1] Other minerals are antimony, arsenic, barytes, bismuth, calcite, cyanite, epidote, fuller's earth, garnet, glauconite, gypsum, lazulite, lead, monazite, platinum, rutile, staurolite, tin, tourmaline, and zinc.[2]

Development work in the mineral deposits of the state in 1902 was confined to gold, silver, and copper, $32,657 being expended. Certain manufacturing industries are closely allied to or are based on the mining industry, using as their raw materials the product of the mine or quarry. The relative importance of these branches of manufacture, as indicated by the value of their products, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$106,654,527
Based upon products of mines or quarries:		
Chemicals and allied products	$3,549,632	
Clay, glass, and stone products	2,483,831	
Iron and steel and their products	4,100,101	
Metals and metal products, other than iron and steel	813,605	
Miscellaneous industries	2,971,110	
		13,918,279
All other		92,736,248

The total value of the products of these manufacturing industries based on mining was, as shown by Table 2, $13,918,279, or 13 per cent of the total value of the product of all manufacturing industries in the state in 1900. During the same year there were employed in all branches of manufactures in the state 83,842 wage-earners, who were paid $20,290,071 in wages. In 1902 there were employed in the mines and quarries of the state 2,820 wage-earners, who received $1,085,047 in wages. Of the combined figures for these two branches of industry, therefore, 96.7 per cent of the wage-earners, receiving 94.9 per cent of the wages, were employed in manufacturing, while 3.3 per cent of the wage-earners, receiving 5.1 per cent of the wages, were employed in mining.

Table 3, compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals of the state from 1890 to 1902.

[1] Georgia, Historical and Industrial, page 135.

[2] Not separately reported.
[3] Includes production from North Carolina.
[4] Silver at commercial value.
[5] Includes production from North Carolina and South Carolina.
[6] Census figures, except for gold and silver.

Siliceous crystalline rocks.—Georgia ranked eighth in the production of the rocks of this group in 1902. Granites and gneisses of excellent quality for building and monumental purposes, and in practically inexhaustible quantities, occur throughout the middle and northeastern parts of the state. One of the most interesting, and perhaps the largest, granite mass in the world is Stone mountain, located in Dekalb county, near Atlanta. This remarkable mountain of rock, whose barren summit attains an altitude of several hundred feet above the surrounding country, with a circumference at its base of 7 miles,[3] has long been the seat of a very important granite industry,[4] the first operations dating back to 1850.[5] The stone obtained from these quarries is a light colored muscovite granite possessing remarkable strength and quite free from all chemical and physical defects. The stone is extensively used as a building material, and is also largely employed in street improvement. There is probably no granite in the South more widely known and more generally used than that furnished by the Stone mountain quarries. Much of it is shipped beyond the borders of the state.[1]

Another granite, or rather granitoid gneiss, of almost as much economic importance as the Stone mountain granite itself, is the lithonia gneiss. This stone, which differs chiefly from the Stone mountain granite in being laminated, occurs in a considerable area in the eastern part of Dekalb county and in the contiguous parts of Rockdale and Gwinnett counties. The quarries on this belt are very extensive and furnish large quantities of

[3] Statistics of Georgia, page 207.
[4] Georgia, Historical and Industrial, page 134.
[5] Stones for Building and Decoration, by George P. Merrill, page 56.

stone for street improvement as well as for general building purposes. Georgia in 1902 ranked first among the states in the production of curbing, of which the greater part was drawn from the quarries on this belt. Granites and granitic gneisses similar to these occur in many other localities in the northern part of the state, but only at a few points have they been quarried to any considerable extent.[1]

In addition to the granites and granitoid gneisses mentioned there are other granites of superior quality which are admirably adapted to monumental purposes. These occur mainly in Elbert and Oglethorpe counties. They are fine grained biotite granites unusually free from injurious minerals and admit of a very brilliant polish. They are perhaps unsurpassed in the United States for decorative stonework, and it is only a question of time when the Georgia monumental granite industry will be of very great commercial value to the state.[1]

Marble.—Georgia ranked second among the states in 1902 in the production of marble. The state's prominence as a marble producer is remarkable, in view of the brief period over which the history of this industry extends. The commercial exploitation of the enormous marble resources has been entirely the work of the last two decades. The outcroppings of snowy rock in Pickens county were known to the Cherokee Indians, who formerly inhabited this region, and by them were worked to a limited extent and cut into bowls and various other forms. A good specimen of this handiwork may still be seen in the form of a large circular marble bowl, now used as a flower pot in a yard near the Piedmont quarries. It is remarkably well preserved, and is valued very highly by its present owner.[2]

The first systematic working of these outcroppings was by Mr. Fritz T. Simmons in 1840, in Longswamp valley near the village of Tate. At first all the work required in getting out and polishing the marble, which was then used exclusively for tombstones, was done by hand. About two years after Mr. Simmons had begun work he erected a mill with one gang of saws on the east bank of Longswamp creek, near Marble Hill post office. This was the first mill put up in the state for sawing marble. This mill was a somewhat primitive affair, but in principle it was identical with the best mills in use at the present day. A small product was turned out in a desultory way by this and similar mills in the vicinity during several years, but the local demand for tombstones was easily satisfied and existing conditions did not, therefore, encourage a rapid growth of the industry. In 1854 operators, who ten years before had opened a quarry 2 miles east of Jasper, renewed the work at that place. They erected a mill with four gangs of saws and continued fairly successful operations until the work was abandoned on account of the Civil War. The product of this mill was sold in the surrounding counties through agents, transportation being effected by wagons.[3] At the close of the war operations were again resumed and continued for about two years. Then followed a period of nearly twenty years during which the marble industry, in common with many others, was at a standstill.

In May, 1884, a company was organized with a capital of $1,500,000.[4] This date marks the beginning of a very important epoch in the history of the development of the marble industry on a commercial scale in Pickens county and the state. Prior to this date Georgia marble was practically unknown to the trade as a building or ornamental stone, and had even a very local use for tombstones, but on account of its exceptional quality and unlimited quantity, and the energy and business-like methods of the operators, it has found its way to all parts of the United States,[4] and even to foreign countries.[5] In many of the finest buildings in the country it has been used for building or ornamental purposes. Among these may be mentioned the capitols of Georgia, Rhode Island, Mississippi, and Minnesota; the United States Government building at Boston; St. Luke's Hospital, New York; and the Corcoran Art Gallery, Washington.[6]

The most valuable marbles of the state are those of the crystalline area, confined in the main to Pickens, Cherokee, Gilmer, and Fannin counties. These marbles occur in a narrow belt which runs parallel to the Atlanta, Knoxville and Northern Railway from near Canton, in Cherokee county, to the Georgia-North Carolina state line, a distance of more than 60 miles. The center of the marble industry of the state is in the vicinity of Tate, Pickens county, just north of the southern end of the belt, where the deposit attains a thickness of 200 feet.[7] The structure of the marble from the different quarries is essentially the same, but there is a marked variation in the color. Some of it is white, some bluish gray with dark blue spots, some with dark blue mottlings, useful for monumental work and interior decorations; others of a variety of shades, such as

[7] Geological Survey of Georgia, Bulletin No. 1, page 21 ff.

pink, salmon, rose, and dark green, thus producing rich effects, are especially adapted for wainscoting, panels, counters, table tops, etc.[1]

In addition to the marbles of the main belt there are also valuable deposits in the northwestern part of the state, especially in Whitfield county. These marbles belong to the same deposits that traverse East Tennessee, which are extensively quarried in the vicinity of Knoxville. The stone has a dark chocolate or light gray color and a rather fine texture. The light gray variety, which is always quite compact and highly crystalline, is traversed by dark zigzag lines that give to the polished surface a very pleasing effect. These marbles, though of great economic value for building purposes, have not as yet been extensively exploited.[2]

Iron ores.—The first iron furnace put into operation in the state was that erected in 1840 on Stamp creek, in Bartow county. Within the following twelve or fifteen years four others were put in blast in the same county. The remains of these old furnaces are still to be seen along Stamp creek and the Etowah river. They were small furnaces of the charcoal type and varied in capacity from 2 to 4 tons a day. The ore was taken from the banks in the vicinity or was picked up from the adjacent fields.[3] The industry, begun on this small scale in Bartow county, rapidly grew in importance and volume until at the opening of the Civil War it had spread to other counties in this immediate section, and with greatly enlarged and improved furnaces the state's output had increased many fold. The passing of the war left the furnaces in ruins, and it was not until 1870 that development of the iron ore deposits of the state was resumed. The Rising Fawn furnace, in Dade county, blowing in for the first time on June 18, 1875, was the first in the United States to use the Whitewell hot blast stove.[4] The industry, however, has never regained its former importance. Three or four modern plants have been manufacturing pig iron in Polk and Floyd counties from the high-grade deposits in the vicinity for a number of years,[5] but the bulk of the crude ore of the state is shipped to the furnaces of other states.[6]

The iron ores of Georgia constitute one of the most valuable of its various mineral products. The deposits, which are quite widely distributed throughout the northern part of the state, consist of the brown ores or limonite, magnetite, and hematite or red ores. The brown ores, which furnish the major portion of the present output, are mined in Bartow, Polk, and Floyd counties. The most abundant deposits of these ores occur in pockets or irregular deposits in the residual clays that have resulted from the weathering of an extensive magnesian limestone formation of the Lower Silurian age, known as the Knox dolomite. The average proportion of metallic iron in these ores runs between 48 and 50 per cent. They occur generally throughout the northwestern part of the state, and to a limited extent in other sections.

The red iron ore is mined in Walker and Chattooga counties.[6] Vast quantities occur in beds which outcrop in sandstone ridges that encircle the Coal Measures or extend parallel with their eastern and western limits.[7] The area underlaid by beds of workable thickness is not less than 350 square miles, and falls mainly within the counties of Dade, Catoosa, Walker, and Chattooga.[8]

The following table, compiled from reports of the United States Geological Survey, shows the output of iron ore from 1890 to 1902, inclusive:

TABLE 4.—*Annual production of iron ores: 1890 to 1902.*

[3] Includes production from North Carolina and South Carolina.

Gold and silver.—Excepting early and half legendary Spanish working in and near the valley of the Coosa, the first gold mining in the state probably began in 1829. In that year, or shortly after, miners from the placer mines of Burke county, N. C., following the indications, went southward into Georgia, where they discovered gold on Dukes creek, in what is now White county. This discovery was followed in quick succession by others throughout Habersham and Lumpkin counties, and soon hundreds of miners were busily engaged on the various streams in this section in search of the yellow metal. In 1830 Governor Gilmer wrote to John McPherson Berrian, then Attorney-General of the United States, saying: "I am in doubt as to what ought to be done with the gold diggers. They, with their various attendants, foragers, and suppliers, make up between six and ten thousand persons. They occupy the country between the Chestatee and Etowah rivers, near the mountains, gold being found in the greatest quantity deposited in small streams which flow into those rivers."[9] The center of gold mining activity then, as now, was in Lumpkin county, in the vicinity of Dahlonega, which in the Cherokee language means "yellow money," and in the town of Auraria, 6 miles away, so named by John C. Calhoun, who owned a mine near by.[10]

[10] The Gold Mines, Scenery, and Climate of Georgia and the Carolinas, by R. C. Stone, page 20.

This region was then known as the Cherokee country, as it was occupied by the Cherokee tribe of Indians. The increasing strife and ill will between the Indians and the white miners, and among the white miners themselves who were quarreling and fighting over the Battle Branch and other gold discoveries, caused Governor Gilmer in June, 1831,[1] to issue a proclamation prohibiting gold mining in north Georgia. A detachment of United States troops was sent to enforce the proclamation. Two miles north of Auraria, or Knucklesville, as it was then called, there was still standing in 1878 the old station house in which General Scott and his troops were stationed to preserve the peace and enforce the law during these turbulent times.[2] Thus the mining industry was temporarily retarded, but the acquisition by the state of the Cherokee country about this time, and the removal of the Indians from it, gave the gold seekers full sway, and a period of great activity immediately ensued.[1] In 1831 the first deposit of gold from the placers of the state was made at the United States Mint.[1] The industry spread rapidly throughout the northern part of the state and the production of gold had reached such volume in 1838 that a branch of the United States Mint was established at Dahlonega. This mint continued in operation for twenty-three years and coined 1,381,784 pieces of gold, valued at $6,115,569. However, much of the product of the state during this period was sent to the Philadelphia and other mints, and the total yield exceeded materially the output of the Dahlonega mint.[3]

Mining activity in the state declined markedly on the discovery of gold in California and ceased almost entirely soon after the opening of the Civil War. As the placer deposits, that gave a basis for the greater part of the industry in its earlier stages, have been largely worked over, attention has been directed more and more in recent years to vein mining. According to the report of the Director of the United States Mint for the year 1882, "the work of the year in Georgia was eminently successful, both in its steady prosecution and increase. New mines were selected with judgment, carefully equipped, and the work for the most part managed with prudence and economy." As a result of the great progress of recent years in deep mining, through the introduction of methods for the economic working of refractory ores, the outlook for the industry in the state is quite promising.[4]

The value of gold and silver produced by the state since the discovery in 1829, as compiled from the reports of the Director of the United States Mint, is $17,105,253.

The gold deposits of the state belong to the Appalachian gold fields, an auriferous belt extending from Nova Scotia to Alabama. In Georgia the belt breaks up into a number of parallels having a northeast-southwest trend. The most important of these are the Dahlonega and the Hall county belts. The Dahlonega belt enters the state from North Carolina in the southwestern part of Rabun county, where valuable placer deposits have been worked at the Smith and Moore Girls mines. Farther to the southwest, in White county, the belt increases in width and the mines become more numerous. As it enters Lumpkin county it again increases in width, reaching its greatest development in the vicinity of Dahlonega. In Dawson county it becomes more or less broken, but upon entering Cherokee it again becomes regular and continues with but few interruptions to the Alabama line. The entire length of this belt is about 150 miles, while its width varies from 1 to 5 miles.

The Hall county gold belt lies some 10 miles east of the Dahlonega belt and parallels it for more than 100 miles, stopping short about 10 miles north of Atlanta. A third belt, which includes the Acworth, Villa Rica, and Bonner mines, traverses Cobb, Paulding, and Carroll counties. Still another belt includes some very important mines in Lincoln, Columbia, McDuffie, and Warren counties, and there are many isolated localities besides in which gold occurs in paying quantities.[5]

Limestones and dolomites.—Limestone suitable for lime, fluxing, and building materials exists in great abundance, especially in the northwestern part of the state. The most extensive of these calcareous formations is the Knox dolomite, a magnesian limestone of great thickness. This formation furnishes much of the lime used in the state as well as a large amount of stone for general building purposes. Other calcareous formations of scarcely less commercial importance are the Bangor and Chickamauga limestones. The Chickamauga stone has been extensively used in the last few years for the foundations of monuments in Chickamauga National Park.[6]

Coal, bituminous.—The coal fields of Georgia, which form the northern extension of the Warrior coal field of Alabama, and which were among the first in the country south of the Ohio river to be worked, are located in the northwestern part of the state, falling in the main within the counties of Dade, Walker, and Chattooga. For fifty years or more mining has been carried on in these fields, the greater part of the product at present coming from Dade and Walker counties.

The coal obtained from all the deposits in the state is an excellent quality of bituminous coal, well suited for coking and steam purposes.

Table 5, compiled from the reports of the United States Geological Survey, shows the annual production from 1884 to 1902, inclusive.

Bauxite.—The first discovery of bauxite in the United States occurred near Rome, Ga., in 1887, and the first bauxite production reported for the country came from the deposits at Hermitage, in Floyd county, in 1889.[1] Shortly after this date other mines were opened in Floyd, Bartow, and Polk counties, so that following close upon its discovery the mining of the bauxite in the state became a very important and lucrative industry. Georgia, until 1891 the only producer of bauxite, still contributes the greater part of this mineral to the market.

All other minerals.—Asbestos is rather widely distributed throughout the northern part of the state, although systematic investigation has been made of the deposits, and hence not much is known of their commercial value or extent. However, for many years the greater part of the supply of this mineral produced in the United States has come from the deposits of Georgia, the mine supplying the most of this being located on Sal mountain in White county.[1]

The industry of mining hydraulic cement rock in the state began in 1845, in Bartow county, above the Western and Atlantic Railroad. The deposits of the state are of excellent quality and are widely distributed over its northwestern part.[2]

The most valuable and extensive deposits of clay in the state are those of sedimentary origin. They occur in a belt several miles in width from Augusta to Columbus. Some of these clays have been used extensively in the manufacture of wall paper, while others are used in making porcelain, terra cotta, tiling, sewer pipe, pottery, etc. Dr. George E. Ladd, director of the Missouri School of Mines, speaking of the cretaceous fire clays of the state, says: "Some of these kaolins suitable for fire clays are more refractory than any of the noted fire clays of the United States." Fire clays also occur in commercial quantities at other points, and residual and alluvial clays, well suited to the manufacture of bricks and the cheaper grades of crockery, abound in every county in the northern part of the state.[3]

Graphite occurs in large quantities in many counties along the western margin of the crystalline area. It is quite abundant in Bartow county, where it is now mined and used in the crude state as a filler for commercial fertilizers.[4]

A light, porous, siliceous stone occurring in Murray, Chattooga, and other counties in northwest Georgia has been known locally for many years as tripoli. Though different from this mineral in origin it has similar uses in the arts.[5]

For many years the mining of manganese ore has been an important industry in the state. During several of the years since 1880 Georgia has been the chief producer of this valuable mineral in the United States, and since that time has contributed more than one-fifth of the total yield of the country.[6] The manganese ores of the state, like the brown iron ores, are confined chiefly to Bartow, Floyd, and Polk counties, the largest and most productive deposit so far located being near Cartersville in Bartow county.[7]

Mica is quite generally distributed throughout the northeastern part of the state, occurring in many places in commercial quantities.[4]

Ocher deposits of commercial value are of wide occurrence throughout the northwestern part of the state, generally associated with the brown iron ores. These ocher deposits, which are really only a pulverulent form of brown iron ore, are quite free from impurities and well suited for making linoleum and paint. The output of the ocher mines of the state, which is about one-fourth of the yield of the country, is shipped in the main to England, where it is used in the manufacture of linoleum.[7]

Pyrite in great abundance is widely distributed throughout the state, but exists in only a few localities in sufficient quantities to be of commercial importance. Valuable and extensive deposits occur in Lumpkin, Paulding, and Haralson counties, but no development on an extensive scale has yet been done.[8]

Sandstone has been extensively quarried in Catoosa county. This variety of sandstone has a dark brown color and resembles very closely the brown sandstone of the Connecticut valley. It makes a beautiful building material and appears to be quite durable. It is also found in great abundance in the mountain ranges of the northwestern part of the state. Other varieties of sandstone of a light color, and well adapted for building purposes, occur in Lookout, Sand, and Pigeon mountains.[9]

The roofing slates of Georgia occur in great quantities in the northwestern part of the state. The center of the slate quarrying industry in the state is at Rockmart, in Polk county, where the industry has been carried on for a great many years.[2]

Talc occurs in the northwestern part of the state in quantities of economic importance and has been mined in a number of places, especially in Fannin county.

IDAHO.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Idaho for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Gold and silver.	Limestones and dolomites.	Sandstones and quartzites.	All other minerals.[1]
Number of mines or quarries	292	258	14	11	9
Number of operators	290	258	13	10	9
Salaried officials, clerks, etc.:					
Number	354	340	.....	1	13
Salaries	$576,690	$550,548	.....	$1,232	$24,910
Wage-earners:					
Average number	3,563	3,382	6	7	168
Total wages	$3,903,504	$3,698,345	$3,964	$4,655	$196,540
Contract work	$43,442	$41,642	.....	.....	$1,800
Miscellaneous expenses	$636,109	$614,670	$110	$615	$21,014
Cost of supplies and materials	$1,626,153	$1,605,696	$1,265	$352	$18,840
Value of product	$8,214,671	$8,177,267	$15,074	$13,777	$8,553

[1] Includes operators as follows: Coal, bituminous, 5; copper, 1; precious stones, 1; siliceous crystalline rocks, 2.

The state ranks fourth in the precious metals, the chief mining industry of the state, and is first in lead production, though the latter occurs as a by-product of gold and silver mining. Gold, silver, and lead mining overshadows all other mine and quarry interests, as the value of these products constituted over 99 per cent of the total mineral products of 1902. The other minerals mined commercially were limestones and dolomites, sandstones, bituminous coal, copper, precious stones, and siliceous crystalline rocks.

Other minerals found in the state, but not reported as mined or quarried in commercial quantities in 1902, are as follows: Antimony, a part of the small amount mined in this country having been furnished by Idaho in 1901 and previous years; marble, which has been quarried to a small extent in former years; mica, mined in former years to some extent in the Roberson mining district, near Moscow, Latah county, and opened up at several other localities;[1] monazite, said to have been found in the gold placers of Oro Fino; nickel ores, reported as occurring at the St. Joe mine, Blackbird, Lemhi county;[2] platinum, which occurs in gold placers of the state;[3] and tungsten ores.[4]

Development work was reported by 325 operators in the gold and silver industry. There were employed on development work 180 salaried officials, clerks, etc., who received $164,560 in salaries, and 852 wage-earners, who were paid $897,412 in wages. There was also paid to 254 employees $158,262 for work done by contract. The miscellaneous expenses amounted to $98,217, and the cost of supplies and materials to $405,058.

The following table shows the value of all manufactured products of this state for 1900 and the value of the products of the manufacturing industries based primarily upon the products of mines and quarries:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.		Value of product.
All manufactures	.....	$4,020,532
Based upon products of mines or quarries:		
Clay, glass, and stone products	$55,709	
Iron and steel and their products	64,272	
Metals and metal products, other than iron and steel	185,347	
Miscellaneous industries	91,448	
		396,776
All other	.....	3,623,756

The value of the products of manufactures utilizing mine and quarry products was 9.9 per cent of the value of all manufactures. Mines and quarries employed 3,563 wage-earners in 1902, who were paid $3,903,504 in wages. In 1900 manufacturers gave employment to 1,477 wage-earners, who received $862,088 as wages. Mines and quarries, therefore, employed 70.7 per cent of the wage-earners of the two industries and paid 81.9 per cent of the wages, and manufactures employed 29.3 per cent of the wage-earners and paid 18.1 per cent of the wages.

[4] Ibid., page 262.

The annual production since 1889 of the leading minerals of the state for which values are reported is shown in the following table:

TABLE 3.—*Value of annual production of principal minerals: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Gold.[1]	Silver.[1]	Limestone.	Sandstone.
1889	$2,000,000	$4,395,959	(2)	(2)
1890	1,850,000	4,783,838	$28,545	$2,490
1891	1,680,000	5,216,970	(2)	(2)
1892	1,721,364	4,475,087	5,000	3,000
1893	1,646,900	5,056,259	1,000	2,005
1894	2,308,775	4,879,966	5,315	10,529
1895	1,779,600	4,021,780	7,829	6,900
1896	2,155,300	6,658,457	5,662	16,060
1897	1,701,700	6,336,905	15,538	(2)
1898	1,716,900	6,560,065	3,080	(2)
1899	1,889,000	4,980,105	3,325	(2)
1900	1,724,700	[3] 3,986,042	34,587	438
1901	1,869,300	[3] 3,325,740	21,251	20,843
1902[4]	1,475,000	[3] 3,103,044	15,074	13,777

[1] Estimates of the Director of the Mint as value of the refined product; silver at coining value. The values given in Table 1 are the values at mine.
[2] Not reported separately.
[3] Commercial value.
[4] Census figures, except for gold and silver.

The mineral production at former census years was confined to gold and silver, with the exception of a small copper output in 1889. The gold and silver returns for the several census years, beginning with 1870, are as follows:

YEAR.	Gold and silver.	YEAR.	Gold and silver.
1870	$1,989,341	1889	$6,040,641
1880	2,430,000	1902	8,177,267

Gold.—Gold was found on the Pen d'Oreille river in 1852 by a French Canadian, but not in paying quantities. The mining growth of the state dates from the discovery of the Oro Fino placer mines in 1860.[1] Other discoveries soon followed. The mines at Florence at the head of Meadow creek were discovered in the fall of 1861; at Boise basin, a very rich placer district, in August, 1862; and at Owyhee in 1863. As in all new gold districts the first mining was placer, the location of the vein mines coming later. The Poorman, one of the famous vein mines of the state, was located in the summer of 1865. The gold and silver production of the state in 1866 was estimated at $17,000,000, but with the exhaustion of the rich placers it fell off rapidly. The following table, compiled from the reports of the Director of the Mint, gives the value of the annual production of gold and silver from 1866 to 1888, inclusive; for the subsequent years it will be found in Table 3.

[1] Report of J. Ross Browne in "Mineral Resources of the United States," 1868, page 517 ff.

TABLE 4.—*Value of annual production of gold and silver: 1866 to 1888.*[1]

[Estimates by the Director of the Mint.]

YEAR.[2]	Gold and silver.	YEAR.[2]	Gold and silver.
1866	$17,000,000	1872	$2,695,870
1867	6,500,000	1873	2,500,000
1868	7,000,000	1874	1,880,004
1869	7,000,000	1875	1,750,000
1870	6,000,000	1876	
1871	5,000,000		

YEAR.	Gold.	Silver.	YEAR.	Gold.	Silver.
1877	$1,500,000	$250,000	1883	$1,400,000	$2,100,000
1878	1,150,000	200,000	1884	1,250,000	2,720,000
1879	1,200,000	650,000	1885	1,800,000	3,500,000
1880	1,980,000	450,000	1886	1,800,000	3,600,000
1881	1,700,000	1,300,000	1887	1,900,000	3,000,000
1882	1,500,000	2,000,000	1888	2,400,000	3,000,000

[1] Silver at coining value.
[2] Figures prior to 1881 taken from The Mineral Industry, 1892, page 188.

The lowest point was reached in 1878, when the total gold and silver production was $1,350,000.

Lead.—Idaho leads all states and territories in lead, on account of the large deposits of argentiferous galenas of the Coeur d'Alene district, which has furnished the major part of the silver and lead product of the state since the first working of the Coeur d'Alene mines in 1886. With the exception of the year 1899, when the product of Coeur d'Alene was reduced by strikes, Idaho has been the first in lead production since 1896. In 1902 the state produced over 30 per cent of the lead product of the country.

Limestones and dolomites.—None of the quarry industries are extensively developed. There were 13 operators—8 individuals and 5 firms—engaged in working 14 limestone quarries in 1902. The value of the product ($15,074) shows the slight and local character of the industry. Of the product, $13,049 was used for lime and $2,025 for flux.

Sandstones and quartzites.—In the sandstone industry 10 operators—7 individuals, 2 firms, and 1 incorporated company—worked 11 quarries. The value of the product was $13,777, composed of building stone, rough, $7,823; dressed, $434; and rubble stone, $5,520.

Coal, bituminous.—Coal was mined in three counties, Lemhi, Fremont, and Boise, to a very small extent, the total production being 2,030 tons of a value of $5,180. The state is the least important of all the coal producing states.

All other minerals.—The state is not a large copper producer, the output for 1902 being less than a quarter of a million of pounds, but the mines of the Seven Devils district have shipped some high-grade ores, and the de-

velopment of copper mines at Mackey, in Custer county, and erection of furnaces, give promise of a material increase in the copper product.

Opals have been found at a number of points in the state and were produced in 1902 to a small extent from one locality in Owyhee county. In 1890 considerable development was commenced near Moscow, Latah county, where opal occurs in the trachyte rocks and production was continued for a year or two. The output for 1891 was estimated at $5,000. Other occurrences are at Opaline, Owyhee county; near Salmon, Lemhi county, where beautiful opal was found in trachyte bowlders and traced to the parent ledge; and at Panther creek, Lemhi county. Smoky quartz in large crystals, up to 4 and 5 inches in diameter, has been found at Brandy creek, in Lemhi county.

Although the state has an abundance of good building material in the granites and other siliceous crystalline rocks, the demand for it is still small. Two quarries were operated to a small extent.

ILLINOIS.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells in the state of Illinois for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Limestones and dolomites.	Cement.	Fluorspar.	Lead and zinc ore.	Clay.	Sandstones and quartzites.	Natural gas.[1]
Number of mines, quarries, and wells	1,116	875	160	6	5	14	8	18	30
Number of operators	1,013	789	150	6	5	14	7	18	24

Number	1,869	1,510	284	50	9	12	2	2	.....
Salaries	$1,910,940	$1,564,832	$270,025	$59,259	$5,304	$9,120	$1,200	$1,200	.....
Wage-earners:									
Average number	40,523	36,617	3,178	488	71	104	42	22	1
Wages	$26,986,397	$24,876,201	$1,737,363	$261,926	$28,845	$51,565	$19,602	$10,295	$600
Contract work	$26,016	$24,699	.....	.....	.....	.....	.....	.....	$1,317
Miscellaneous expenses	$1,543,903	$1,258,686	$233,379	$35,621	$1,149	$11,079	$1,999	$1,946	$44
Cost of supplies and materials	$3,515,833	$2,834,444	$451,908	$185,881	$17,115	$20,464	$3,916	$1,955	$150
Value of product	$38,234,410	$33,945,910	$3,232,123	$769,251	$123,000	$90,619	$38,463	$32,200	$2,844

[1] Includes petroleum, 1 operator (2 wells).

The coal deposits underlie an extensive area and are part of the Central coal field, which includes Indiana and western Kentucky.[1] The lead mines of the Galena district have been in operation for nearly, if not quite, a century, but to-day more zinc than lead ore is produced. The Niagara limestone of Lemont and Joliet is a fine grained, workable stone, much in demand in the interior states. A good quality of sandstone is also found. Until quite recently the fluorspar mines in the southern part of the state were the only source of supply of this mineral in the United States. There are some petroleum and natural-gas wells, good clay is plentiful, and Portland cement is manufactured in large quantities.[2]

In addition to the minerals referred to in Table 1, iron ore and mineral pigments occur in the state, but were not produced in commercial quantities in 1902. The state ranked sixth in mines and quarries in 1902 according to value of product.

Table 2 presents the value of production of the manufacturing industries of this state, which are based primarily upon the products of mines and quarries, and also the value of all manufactured products in Illinois, as reported to the Twelfth Census.

[1] United States Geological Survey, "Mineral Resources of the United States," 1902, page 292.

[2] King's Handbook of the United States, pages 206 and 207.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$1,259,730,168
Based upon products of mines or quarries:		
Chemicals and allied products	$9,928,333	
Clay, glass, and stone products	19,208,163	
Iron and steel and their products	160,189,237	
Metals and metal products, other than iron and steel	50,170,581	
Miscellaneous industries	57,436,587	
		296,932,901
All other		962,797,267

The value of the products of manufactures, based primarily upon minerals mined or quarried, as shown by the foregoing table, was $296,932,901, or 23.6 per cent of the total. The value of the total product of mines, quarries, and wells of Illinois in 1902, and manufactures in 1900, was $1,297,964,578, of which manufactures contributed 97 per cent and mines and quarries 3 per cent.

The Twelfth Census shows that on the average 395,110 wage-earners were engaged in manufactures in Illinois in 1900, and that $191,510,962 was paid in wages. The average number of wage-earners engaged in mining in 1902 was 40,523, and the wages paid amounted to $26,986,397. The two industries together

gave employment to 435,633 wage-earners during the year, and paid $218,497,359 in wages. Manufactures gave employment to 90.7 per cent of these wage-earners, and paid 87.6 per cent of the wages, while mining employed but 9.3 per cent of the wage-earners, and paid only 12.4 per cent of the wages.

The following table, compiled from the reports of the United States Geological Survey, shows the value of the production of the leading minerals, except for lead and zinc, for which values can not be obtained, from 1890 to 1902:

TABLE 3.—*Value of annual production of the principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Limestones and dolomites.	Portland cement.	Natural rock cement.	Fluorspar.
1890	$14,171,230	$2,190,607	(1)	[2] $292,784	$55,328
1891	14,237,074	2,030,000	(1)	[2] 276,931	78,330
1892	16,243,645	3,185,000	(1)	[2] 236,438	89,000
1893	17,827,595	2,305,000	(1)	153,039	84,000
1894	15,282,111	2,555,952	$540	133,880	47,500
1895	14,239,157	1,687,662	1,325	171,854	24,000
1896	15,809,736	1,261,359	5,250	217,731	[3] 52,000
1897	14,472,529	1,483,157	26,250	209,000	[3] 37,159
1898	14,567,598	1,421,072	(1)	220,580	(1)
1899	20,744,553	2,065,483	79,500	187,983	[3] 96,650
1900	26,927,185	1,881,151	300,552	129,446	[3] 94,500
1901	28,163,937	2,793,837	581,818	187,936	[3] 113,803
1902 [4]	33,945,910	3,232,123	769,251	(5)	123,000

[1] No production reported.
[2] Includes value of packages.
[3] Includes production from Kentucky.
[4] Census figures.
[5] Included in Portland cement.

Coal.—The bituminous coal deposits in Illinois underlie some 35,000 square miles, or about 63 per cent of the area of the state. The coal field extends from the northern boundary of Grundy county west to the Mississippi river, near Rock Island, and south along the Mississippi to the north line of Henderson county, where it leaves the river and inclines eastward to the southern part of Jackson county. Although the first discovery of coal in the United States was made in Illinois by Father Hennepin in 1679, near the present city of Ottawa, there is no probability that any mines were opened in that locality until long after coal mining had begun in the southern part of the state. The first record of coal mining in the state was in 1810, in Jackson county. In 1832 several boat loads were shipped from this locality to New Orleans, and in 1833, 6,000 tons were mined in St. Clair county and taken to St. Louis.[1] Since that date there has been a continual increase in the coal production.

In 1902 coal was mined in 54 counties, 41 of which showed an increase in production over 1901 and 7 a decrease, the remaining 6 counties not being reported in 1901. Sangamon, with an output of 4,172,722 tons, ranked first among the coal producing counties; St. Clair second, with 2,822,248; and Vermilion third, with 2,585,291 tons. Other large coal producing counties are Bureau, Grundy, Lasalle, Macoupin, Madison, and Williamson; each have a production exceeding 1,000,000 tons. Illinois ranked second among the coal producing states.

The 789 coal operators gave employment during 1902 to 36,617 wage-earners, or 90.4 per cent of all wage-earners engaged in mines and mining in the state during the year. They also paid in wages $24,876,201, or 92.2 per cent of all the wages paid in the mining industries of the state.

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of coal in Illinois since 1833:

TABLE 4.—*Annual production of coal, bituminous: 1833 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.
1833	6,000	1868	2,000,000
1834	7,500	1869	1,854,000

Limestones and dolomites.—Illinois ranked second among the limestone producing states, the products of its quarries in 1902 being valued at $3,232,123. The rocks represent most of the epochs of the Silurian, Devonian, and Carboniferous ages. A notable limestone is quarried in Will county, in the vicinity of Lemont and Joliet; it is a fine grained, light colored Niagara stone, soft and easily worked, taking readily a smooth surface, but no polish.[2]

Of the 160 producing quarries, 55 had a production valued in excess of $10,000, and only 7 produced stone valued in excess of $100,000. Cook county, with an output valued at $1,418,408, ranked first among the 30 limestone producing counties; Will county second, with a production valued at $485,268; and Kankakee county third, with $256,017.

[1] Illinois Bureau of Labor Statistics, Twenty-first Annual Coal Report, 1902, page 1.

[2] Stones for Building and Decoration, by George P. Merrill, page 297.

Cement.—A fine quality of magnesian limestone was discovered at Utica, Lasalle county, in 1838, during the construction of the Illinois and Michigan canal, and in the same year a factory was erected for the production of natural rock cement. This plant is still successfully operated. A second factory was built in 1869 at Lasalle, and has since been in continuous operation. The manufacture of Portland cement was first reported from Illinois in 1894, at Oglesby, Lasalle county.[1]

In 1902 there were 4 Portland cement plants in this state. Illinois ranked sixth among the states producing Portland cement at the time of this report.

The following figures from the reports of the United States Geological Survey show the production of cement in this state since 1894:

TABLE 5.—*Annual production of cement: 1894 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

1902	767,781	607,820

[1] No production.

Fluorspar.—That this mineral was known long ago is proved by the discovery of fluorspar shaped into ornaments in some of the prehistoric mounds of southern Illinois. The earliest scientific mention of its occurrence was in 1819, which describes specimens obtained in the vicinity of Shawneetown. It was first discovered in Hardin county in 1839, and in 1842–43 mining was first actually commenced. The deposits of fluorspar and galena of Hardin county occur in the limestones which underlie the Coal Measures of the states bordering on the Ohio river.[2] Until 1898 the Hardin county mines near Rosiclare and those in Pope county supplied all the fluorspar produced in the United States,[3] but since 1900 Kentucky has led Illinois in the output of this mineral. A small quantity of fluorspar was produced in Pope county, Ill., in 1902.

The following figures from the reports of the United States Geological Survey show the production of fluorspar in Illinois since 1882, the figures since 1895 being combined with those for Kentucky:

TABLE 6.—*Annual production of fluorspar: 1882 to 1902.*

1892	12,250		

[1] Includes Kentucky. [2] No production reported.

Lead and zinc ore.—The lead bearing district in the northwestern corner of the state is entirely comprised within the limits of Jo Daviess and Stephenson counties.[4] This district forms a part of the upper Mississippi lead region, which occupies an area of some 3,000 square miles in Wisconsin, Iowa, and Illinois. Lead is supposed to have been observed at several points along the Mississippi river by Le Sueur in 1700, and the lead region of the upper Mississippi was located on a map published in France in 1752. Mining of lead ore in Illinois was probably not in active progress much before 1827,[5] the period of greatest production being from 1840 to 1850.[6] Galena, in Jo Daviess county, has always been the center of lead mining in Illinois, and up to the completion of the railroads was the natural outlet for the lead mined in Wisconsin. Zinc did not come into the market until 1860,[7] since which time its production has increased until it is now much greater than that of lead. In 1902 the production of zinc ore in Illinois amounted to 2,778 tons, while that of lead ore was only 792 tons.

Clay.—The state ranked thirteenth in the production of clay in 1902 according to value, producing 1.9 per cent of the total for the United States. The value of the clay produced by the 7 operators was $38,463.

[7] Iowa Geological Survey, Vol. VI, page 18.

Sandstones and quartzites.—Carboniferous sandstones of light and dark brown color and good quality are found near Carbondale, Jackson county. The stone is of medium texture, works readily, and closely resembles some of the Connecticut brownstones.[1] The 18 sandstone quarries operating in Illinois in 1902 were located in Alexander, Carroll, Clay, Fulton, Henry, Jackson, Lee, St. Clair, Whiteside, and Union counties, and produced an output valued at $32,200.

[1] Stones for Building and Decoration, page 138.

30223—04——14

Natural gas.—Natural gas was first discovered in Illinois in Champaign county in 1853. In later years it has been found in many other counties, but the wells generally have been shallow.[2] The natural gas of the state in 1902 came from the wells in Randolph and Bureau counties, the entire production being valued at only $1,844.

There were two petroleum wells in Illinois in 1902. The maximum production of petroleum in the state, 1,460 barrels, was recorded in 1889.

[2] United States Geological Survey, "Mineral Resources of the United States," 1902, page 759.

INDIAN TERRITORY.

Table 1 is a summary of the statistics for the productive mines, quarries, and natural-gas and petroleum wells in Indian Territory for 1902.

TABLE 1.—*Summary: 1902.*

	Total.	Coal, bituminous.	Asphaltum and bituminous rock.	All other minerals.[1]
Number of mines, quarries, and wells	79	58	6	15
Number of operators	39	29	6	4
Salaried officials, clerks, etc.:				
Number	260	248	5	7
Salaries	$253,171	$240,581	$4,410	$8,180
Wage-earners:				
Average number	4,814	4,763	28	23
Wages	$3,183,322	$3,154,267	$13,185	$15,870
Contract work	$78,639	$56,610	$1,029	$21,000
Miscellaneous expenses	$366,332	$358,960	$2,213	$5,159
Cost of supplies and materials	$329,063	$320,664	$6,299	$2,100
Value of product	$4,321,380	$4,265,106	$11,754	$44,520

[1] Includes operators as follows: Natural gas, 1; petroleum, 2 (13 wells); and siliceous crystalline rocks, 1.

Investigations as to the geological conditions and formations of Indian Territory began as early as 1819[1] and have been continued from time to time during later years. In 1853 the geologist of the Pacific Railroad expedition, Jules Marcou, made an important reconnaissance of the southern part and gave to the public a better knowledge of the lithology and structure of coals in this vicinity.

Of the total mineral production for 1902 in Indian Territory, 98.7 per cent was coal, bituminous, and the remainder was asphaltum and bituminous rock, natural gas, petroleum, and siliceous crystalline rocks. Considerable development work, chiefly in coal mining, was carried on during the year, $167,261 being expended for this purpose. Copper and gold ores[2] are known to exist in the Wichita mountains, although they were not mined in commercial quantities in 1902. Sandstones and quartzites extend over a large portion of the territory,[1] and limestones and dolomites are found north of the Arkansas river. No sandstone or limestone production was reported during 1902.

The following table presents the value of the products of those manufacturing industries which are based primarily upon the products of mines and quarries and also the total value of the products of manufactures in Indian Territory in 1900:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$3,892,181
Based upon products of mines or quarries:		
Clay, glass, and stone products	$70,214	
Metals and metal products, other than iron and steel	54,544	
Miscellaneous industries	121,921	
		246,679
All other		3,645,502

The value of the output of the manufactures based primarily upon the products of mines and quarries, as shown in the above table, amounted to $246,679, or 6.3 per cent of the total value of the manufactured product of the territory for 1900, indicating that manufacturing in Indian Territory is but slightly dependent upon mineral industries for its raw or partially manufactured material.

In 1902 there were employed in mining and quarrying in Indian Territory an average number of 4,814 wage-earners who received the sum of $3,183,322 in wages. During the census year of 1900 there was an average number of 1,714 wage-earners engaged in manufactures in the territory, and they received $553,899 in wages. The combined manufacturing and mining industries gave employment to 6,528 wage-earners, who received $3,737,221 in wages. The mines and quarries employed 73.7 per cent of the total number of wage-earners and paid 85.2 per cent of the total wages, while the manufacturing industries employed 26.3 per cent of the total number of wage-earners and paid 14.8 per cent of the combined wages.

Coal, bituminous.—Coal mining is by far the most important mineral industry in Indian Territory. The coal fields occupy all of the area of the Creek nation and parts of the area of the Cherokee, Chickasaw, and Choctaw nations, a total of about 20,000 square miles.[3] These fields bear an intimate relation to the Coal Measures of Oklahoma, Kansas, Arkansas, and part of Texas.[4]

[1] A Geological Reconnaissance of the Coal Fields of Indian Territory, by Noah F. Drake, Ph. D., page 327.

[2] United States Geological Survey, "Mineral Resources of the United States," 1887, page 730.

[3] United States Geological Survey, Twenty-second Annual Report, 1900–1901, Part III, page 373.

[4] A Geological Reconnaissance of the Coal Fields of Indian Territory, page 360.

The development of coal deposits adjacent to McAlester, began in 1872,[1] where a coal suitable for coking was obtained. In 1881 operations were commenced in the vicinity of Savanna and Lehigh,[1] and in 1885 the first commercial coal production was reported in Indian Territory, amounting to 500,000 short tons.

The following table gives the annual production and value of bituminous coal mined in Indian Territory:

TABLE 3.—*Annual production of coal, bituminous: 1885 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Quantity (short tons).	Value.	YEAR.	Quantity (short tons).	Value.
1885	446,429	$750,000	1894	969,606	$1,541,293
1886	534,580	855,328	1895	1,211,185	1,737,254
1887	685,911	1,286,692	1896	1,366,646	1,918,115
1888	761,986	1,432,072	1897	1,336,380	1,787,358
1889	752,832	1,323,807	1898	1,381,466	1,827,638
1890	869,229	1,579,188	1899	1,537,427	2,199,785
1891	1,091,032	1,897,037	1900	1,922,298	2,788,124
1892	1,192,721	2,043,479	1901	2,421,781	3,915,268
1893	1,252,110	2,235,209	1902[1]	2,820,666	4,265,106

[1] Census figures.

The above table shows a steady increase in annual production, with the exception of the years 1889, 1894, and 1897, from the time of the first commercial mining operations up to 1902.

The coal belt is about 65 miles wide where it enters from Kansas near the northeast corner of Indian Territory. It extends southward through the territory and then eastward in an L-shaped formation into Arkansas. The southern branches of Coal Measures, reaching into Texas, are somewhat broken by a covering of Cretaceous deposits.

The coal seams vary considerably in thickness in the different portions of the territory, in some instances being too thin for profitable working. The coal deposits worked near Lehigh and Savanna[2] vary from 3 feet 11 inches to 4 feet 2 inches in thickness, while those of the McAlester district vary from 3 feet 6 inches to 4 feet.

The product of the Lehigh and Savanna mines is more especially adapted to steaming purposes[3] and both these coals are considerably utilized by railroads[4] while the McAlester product is a high-grade coke and gas coal remarkably free from sulphur and other impurities. The Savanna product somewhat resembles[3] that of the McAlester district, but the Lehigh coal, although of good steaming qualities, is not adapted for coking.

Asphaltum and bituminous rock.—The region of asphaltum and bituminous rock deposits in Indian Territory[5] is entirely south of the Canadian river and extends from the eastern to the western boundary of the territory.[6] The asphaltite of eastern Indian Territory is generally of a vein forming variety, jet black in color and brilliant in lustre, and of an exceeding brittleness.

One or two quarries were operated during 1895, but the experiment was not a complete success[7] owing to the hard and irregular formation of the asphaltic lime rock. Further developments have been more successful. In 1898 and 1899[8] new discoveries of asphaltic limestone and sandstone were made in the district adjacent to Dougherty and Davis, and a considerable production, chiefly of mastic, was reported. There were 6 quarries in operation during 1902 reporting a production valued at $11,754; in addition a considerable amount of development work was done by one company.

All other minerals.—One natural gas well was reported in the Creek nation and a considerable product was also obtained from an idle petroleum well in the same locality. As there was but one report, the statistics for natural gas production for Indian Territory can not be separately shown.

There were 13 petroleum wells reported by 2 companies near Bartlesville in the Osage nation and a large product was secured in 1902. Development work is being actively carried on in this vicinity.

One granite quarry was reported for the Chickasaw nation with a large production in 1902. The product is not shown separately, as to do so would disclose the operations of an individual establishment. The granite quarried in Indian Territory is not sold in the rough, but is dressed for building purposes and monumental work or prepared for curbing or concrete before it is placed on the market.

INDIANA.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells in the state of Indiana for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Natural gas.	Petroleum.	Limestones and dolomites.	Cement.	Sandstones and quartzites.	All other minerals.[1]
Number of mines, quarries, and wells	16,825	339	6,861	9,439	160	9	9	8
Number of operators	3,909	283	880	2,567	156	7	9	7
Salaried employees:								
Number	1,662	637	580	108	266	65	6	.....
Salaries	$1,430,538	$530,492	$447,508	$138,536	$238,186	$71,166	$4,650	.....
Wage-earners:								
Average number	16,473	10,593	938	1,463	2,834	568	41	36
Wages	$10,729,767	$7,396,425	$586,860	$1,045,925	$1,399,829	$266,949	$19,567	$14,212
Contract work	$2,164,380	$26,603	$1,046,444	$1,091,333	.....	.....	.....	.....
Miscellaneous expenses	$3,387,668	$449,054	$1,399,355	$1,286,499	$196,907	$53,447	$1,706	$700
Cost of supplies and materials	$3,810,666	$729,104	$1,028,358	$1,126,627	$499,764	$420,168	$3,040	$3,605
Value of product	$28,224,760	$10,399,660	$7,081,344	$6,526,622	$2,865,691	$1,266,228	$37,593	$27,622

[1] Includes operators as follows: Clay, 2; oilstones, whetstones, and scythestones, 5 (6 mines); sulphur and pyrite (all data except value of product included with coal, bituminous).

The coals of this state, underlying 7,000 square miles or one-fifth the area of the state, are mostly bituminous, although some block coal is also mined. The petroleum area is steadily increasing, and the natural gas production places Indiana second among states reporting this product. No state possesses better stone for building purposes than Indiana. The production includes the Bedford limestones and the sandstones comprising the so-called conglomerate. Indiana is a large producer of whetstones, the Hindostan whetstone rock having been used for years. The clay deposits are very valuable, and are found in some form in every county. Quantities of white sand suitable for glassmaking occur in various localities. Limonite and siderite iron ore have been found in large quantities in several counties, but they are too siliceous to compete with the rich beds of hematite in other states. The marl deposits are being used more and more in the manufacture of cement.[1]

In addition to the productive mines, quarries, and wells referred to in Table 1, 12 operators reported active mines and wells but no production. These operators paid but $269 in wages during the year, practically all the work being done by contract. For such work $21,979 was paid. Miscellaneous expenses amounted to $6,417, and cost of supplies and materials to $9,118.

The following table shows the value of the products of the manufacturing industries, based primarily upon minerals mined and quarried, and also the total value of the products of all manufactures of Indiana, as reported to the Twelfth Census:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures	.....	$378,120,140
Based upon products of mines or quarries:		
Chemicals and allied products	$18,113,023	
Clay, glass, and stone products	22,843,090	
Iron and steel and their products	50,884,844	
Metals and metal products, other than iron and steel	4,523,881	
Miscellaneous industries	13,182,452	
	.....	109,547,290
All other	.....	268,572,850

The value of the products of manufactures, based primarily upon minerals mined and quarried, as shown by the foregoing table, is $109,547,290, or about 29 per cent of the total. The total value of the product of mines, quarries, and wells of Indiana in 1902 and manufactures in 1900 was $406,344,900, of which manufactures contributed 93.1 per cent and mines and quarries 6.9 per cent.

The average number of wage-earners reported by the Twelfth Census as engaged in manufacturing was 155,956, and the wages paid were $66,847,317. The average number of wage-earners engaged in mines and quarries in 1902 was 16,473, and the wages paid amounted to $10,729,767.

The two industries combined gave employment during the year to 172,429 wage-earners and paid $77,577,084

[1] Indiana Department of Geology and Natural Resources, Twentieth Annual Report, 1895, pages 16 to 20.

in wages. Manufactures gave employment to 90.4 per cent of the wage-earners and paid 86.2 per cent of the wages, while mines and quarries employed only 9.6 per cent of the wage-earners and paid 13.8 per cent of the wages.

The following table shows the value of the annual production of the leading minerals of the state, 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal.	Natural gas.	Petroleum.	Limestones and dolomites.	Portland cement.	Sandstones and quartzites.
1890	$3,259,233	$2,302,500	$32,462	$1,889,336	(1)	$43,983
1891	3,070,918	3,942,500	54,787	2,100,000	(1)	90,000
1892	3,620,582	4,716,000	260,620	1,800,000	(1)	80,000
1893	4,055,372	5,718,000	1,050,882	1,474,695	(1)	20,000

[1] No production. [2] Census figures. [3] Includes natural rock cement.

Coal.—The coal area is found in the western and southwestern part of the state, and ranges from 10 to 60 miles in width. The veins of workable thickness vary from 3 to 11 feet, but are in a few places from 25 to 28 feet thick.[1]

The Eastern Interior or Central coal field includes not only the bituminous coal areas of Indiana, but also those of Illinois and western Kentucky; in point of production it ranks second among the bituminous coal producing fields. Father Hennepin first found coal in this field in 1698 on the Illinois river, near Fort Crève-Cœur. This is the first mention of coal found in America. In 1804 coal was noted in the course of land surveys of Indiana, and its position marked on the maps. In 1811 coal dug at Fulton, Perry county, was used by Robert Fulton on the steamboat *Orleans*, and from 1830 to 1860 coal was shipped in a small way out of the state.[2] Since 1860 the mining of coal has steadily increased, and in 1902 Indiana ranked sixth among the bituminous coal producing states, with a total production of 9,446,424 short tons, of which 1,101,544 tons was block coal.

Of the 18 coal producing counties of Indiana in 1902, 13 show an increased production over 1901, the increase in Greene county, 719,164 short tons, being particularly noticeable. Greene county stands first, with a total production of 1,663,785 tons; Vigo second, with 1,652,798 tons; and Clay third, with 1,315,046 tons. Parke and Sullivan counties also contributed over 1,000,000 tons each.

Since 1870 the production of coal in Indiana has amounted to 96,060,655 short tons, as shown in the following table:

TABLE 4.—*Annual production of coal, bituminous: 1870 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

1885	2,375,000		

Natural gas.—Although the existence of natural gas in Indiana was known, it was not until after the Trenton rock gas field was opened at Findlay, Ohio, in 1884, that any great attention was given to its development.[3] The knowledge that large quantities of high pressure gas were stored within the Trenton limestone caused a rapid development in this industry. Twenty-six counties contributed to the production in 1902.

Petroleum.—The earliest production of petroleum in commercial quantities was first recorded in Vigo county in 1889.[4] The main Indiana oil field is a continuation of the Lima field in Ohio and extends from the Ohio-Indiana state line westward to Marion, Grant county, and from Warren, Huntington county, south to Hartford City, Blackford county. The greatest length of the field is about 45 miles and its extreme width about 20 miles.[5]

The following table compiled from the reports of the United States Geological Survey shows the annual production of petroleum in Indiana since 1889:

TABLE 5.—*Annual production of petroleum: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

Limestones and dolomites.—The limestones of Indiana, which are quarried for building purposes, belong either to the Upper Silurian or Subcarboniferous formations in the central and southern parts of the state. The most beautiful and valuable of the oolitic limestones found in Lawrence, Monroe, Owen, Crawford, Harrison, and Washington counties, is that known as "Bedford stone," found near Bedford, in Lawrence county. This rock is of fine, even texture, and is composed of small rounded grains compactly cemented together by crystalline lime or calcite. The stone is soft but tenacious, works readily in every direction, and is used more for carved work than any other domestic limestone.[1]

Of the 36 limestone producing counties of Indiana in 1902 only 6 had an output valued in excess of $100,000. Lawrence county ranked first with a production valued at $1,207,497, or about 42 per cent of the total for the state, which was $2,865,691. Monroe county ranked second and Decatur third.

Cement.—The first Portland cement plant in Indiana, and one among the first in the United States, was constructed at South Bend in 1877. In 1893 this plant was shut down and has not since been a successful producer. In 1900 a new plant was completed at Stroh, Lagrange county, which has since been an increasingly successful producer.[2] Late in the same year another plant was completed near Syracuse, Kosciusko county, but no production was reported until 1901. In 1902 the first production from the plant at Mitchell, in Lawrence county, was reported.[3] In 1900 the single Portland cement plant in Indiana produced 30,000 barrels. In 1901 the two plants produced 218,402 barrels, and in 1902 the three plants produced 536,706 barrels.[3]

Natural cement rock in Indiana was first noticed in Clark county during the construction of the Louisville and Shippingsport canal about 1826. Some time after 1832 a flouring mill, built at Clarksville, Ind., in that year, was changed into the first cement mill to be operated in the state.[4] In 1902 the six plants in Clark county produced 1,343,185 barrels of natural rock cement, valued at $657,984.

Sandstones and quartzites.—The Mansfield sandstone, coarse grained, and gray, yellow, red, brown, or variegated in color, is probably the most important sandstone in the state.[4] The value of the total output of sandstone in Indiana for 1902 was $37,593.

All other minerals.—The value of the clay produced by the two operators who reported, is included with that for other states in order to avoid disclosing individual operations.

The Hindostan whetstone of Orange county is said to have been first discovered in 1810 and the first quarry was opened in 1825.[4] The value of the finished product from the six quarries operated in 1902 was $16,950.

There was a small production of pyrite in Indiana in 1902, which was a by-product of coal mining.

IOWA.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Iowa for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Limestones and dolomites.	Gypsum.	Sandstones and quartzites.	Lead and zinc ore.
Number of mines or quarries	625	326	244	9	32	14
Number of operators	589	299	241	3	32	14
Salaried officials, clerks, etc.:						
Number	610	512	76	20	1	1
Salaries	$500,126	$436,828	$46,775	$15,883	$360	$280
Wage-earners:						
Average number	10,437	9,439	680	293	12	13
Wages	$6,791,161	$6,251,732	$357,249	$170,828	$5,586	$5,766
Contract work	$48,106	$48,046	$60			
Miscellaneous expenses	$373,252	$341,191	$22,518	$6,505	$527	$2,511
Cost of supplies and materials	$961,996	$841,506	$71,361	$47,683	$527	$919
Value of product	$9,676,424	$8,660,287	$649,984	$337,734	$15,061	$13,358

The bituminous coal deposits of Iowa underlie some 20,000 square miles in the southern half of the state and are a part of the Western Interior coal field. Over 10,000 wage-earners are now employed in the coal mines.[1] Large quantities of lead and zinc ore occur in the northeastern part of the state, around Dubuque, but at the present time these minerals are but little mined.[2] The gypsum deposits form one of the most valuable of Iowa's mineral resources.[3]

In addition to the minerals mentioned in Table 1 iron ore and mineral paints are found in Iowa, but these were not produced in commercial quantities in 1902.

Table 2 shows the value of the products of the manufacturing industries, based primarily upon minerals mined and quarried, and also the value of all manufactured products in Iowa, as reported at the Twelfth Census.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$164,617,877
Based upon products of mines or quarries:		
Chemicals and allied products	$342,707	
Clay, glass, and stone products	4,430,652	
Iron and steel and their products	6,198,884	
Metals and metal products, other than iron and steel	2,655,415	
Miscellaneous industries	6,964,093	
		20,591,751
All other		144,026,126

As shown in the foregoing table the value of the products of the manufacturing industries, based primarily upon minerals mined and quarried, was $20,591,751, or about 12.5 per cent of the total value of all manufactured products. The value of the output of the mines and quarries of Iowa for 1902 was $9,676,424, or 5.9 per cent of the total value of product of all manufacturing and mining industries.

The average number of wage-earners engaged in manufactures, as reported at the census of 1900, was 58,553, and the wages paid amounted to $23,931,680. The average number of wage-earners engaged in mining in 1902 was 10,437, and the wages paid were $6,791,161. The manufacturing and mining industries combined, therefore, gave employment during the year to 68,990 wage-earners and paid $30,722,841 in wages. Of these totals, manufactures employed 84.9 per cent of the wage-earners and paid 77.9 per cent of the wages, and mines and quarries employed 15.1 per cent of the wage-earners and paid 22.1 per cent of the wages.

The following table shows the value of the annual production of the principal minerals, 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

Coal.—The area of the coal fields of Iowa is about 20,000 square miles, of which probably one-half is productive.[1] Coal has, without doubt, been mined since the earliest settlement of this area, but no production is recorded prior to 1840, and it was not until after 1852[2] that coal was mined for other than local use.

Of the 24 coal producing counties in 1902, Monroe was first, with 1,406,905 tons; Polk second, and Appanoose third. Other counties having a production in excess of 100,000 tons are Boone, Jasper, Keokuk, Lucas, Mahaska, Marion, Wapello, and Webster.

The figures in the following table are compiled from the reports of the United States Geological Survey, and show the annual production of coal in Iowa since 1840:

TABLE 4.—*Annual production of coal, bituminous: 1840 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.	YEAR.	Short tons.

1858	37,500	1880	1,461,166	1902	5,904,766
1859	42,000	1881	2,500,000		

Limestones and dolomites.—Although limestones and dolomites abound in this state to the exclusion of almost all other varieties of building stone, but little of the material now quarried acquires more than a local reputation.[3] The quarries of the Stone City district in Jones county produce the well-known Anamosa limestone, which was first shipped to any distance in 1859.[4] This stone has found special favor for bridge masonry. Among the 45 counties in which limestone was quarried Jones county ranks first in the value of its output, Jackson county second, and Cedar county third.

Gypsum.—Although the occurrence of gypsum in Iowa has been known for many years, its extent and value has been recognized only recently. To-day it may be considered as forming one of the deposits of greatest value among Iowa's mineral resources.[5] An area of nearly 50 square miles, near Fort Dodge, in Webster county, is known to be covered by the gypsum beds, and this is probably one of the most valuable formations of the kind in the United States.[5] The total amount of available gypsum on the known area is more than 40,000,000,000 tons, and at the present rate of production the supply will last not less than 800,000 years.[5] Nearly the entire production is converted into stucco, or plaster of Paris.

The following table shows the production of gypsum in Iowa since 1889, the figures being compiled from the reports of the United States Geological Survey:

TABLE 5.—*Annual production of gypsum: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.
1889	21,784	1896	18,631

1891	31,385	1898	24,733
1892	12,000	1899	75,574
1893	21,447	1900	184,600
1894	17,906	1901	[1]213,419
1895	25,700	1902	120,779

[1] Includes production from Kansas and Texas.

Sandstones and quartzites.—The 32 quarries operating in 1902 were located in Blackhawk, Cerro Gordo, Clayton, Clinton, Decatur, Des Moines, Fayette, Hardin, Jones, Keokuk, Lee, Marion, Scott, Tama, Van Buren, and Webster counties.

Lead and zinc ore.—The upper Mississippi lead and zinc region, comprising within its limits about 3,000 square miles,[6] embraces the southwest portion of Wisconsin, the northwest corner of Illinois, and the adjoining portion of Iowa, in the counties of Dubuque, Allamakee, and Clayton.

In 1700 Le Sueur is supposed to have observed lead at several points along the Mississippi river, and in 1752 the lead region of the upper Mississippi was located on a map published in France during that year. In 1788 the first mining of lead ore in Iowa was carried on by Julien Dubuque, who had obtained from the Indians a grant or lease of land for mining in what is now Dubuque county. Dubuque continued to develop his prospects until his death in 1810. The most productive period of the Dubuque mines was probably during the years 1835 to 1849.[7]

It was not until 1860[6] that zinc was produced commercially in Iowa. Since then its production has increased until it is greater than that of lead. In 1902 the 14 mines then in operation produced 186 tons of lead ore and 376 tons of zinc ore.

[1] Includes operators, as follows: Cement, 2; gypsum, 5 (7 quarries).

The coal mines of the state compare favorably with those of other coal producing states in the Mississippi valley and the yearly output is increasing. In zinc smelting Kansas ranks second among the states and its lead and zinc mines, although confined to but a few square miles in area, produce annually a large quantity of these ores. The fields of natural gas and petroleum are extensive and are being rapidly developed. The gypsum deposits are large and quantities of cement plasters are manufactured and shipped to all parts of the United States.[1] The manufacture of cement is also a growing industry.

In addition to the minerals referred to in Table 1, clay suitable for the manufacture of tiles, brick, and low-grade pottery, and barite are found in the state, but were not produced in commercial quantites in 1902.

The 18 operators reporting development work, distributed among the industries of natural gas, petroleum, lead and zinc, and coal (bituminous), gave employment during the year to 16 salaried officials, clerks, etc., who received $5,892 in salaries; and to 19 wage-earners, who were paid $16,463 in wages. They also paid $97,511 for work done by contract, which furnished employment to 78 employees. The miscellaneous expenses amounted to $10,956, and the cost of supplies and materials to $90,685.

Table 2 shows the value of the products of the manufacturing industries of the state, based primarily upon the products of mines and quarries, and also the value of all products manufactured in Kansas in 1900.

According to the following table, the value of the products of manufactures, based primarily upon minerals mined and quarried, amounted to $37,060,148, or 21.5 per cent of the total. The combined value of the product of mines and quarries in 1902 and of manufactures in 1900 was $182,829,683, of which manufactures contributed 94.1 per cent and mines and quarries 5.9 per cent.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.		Value of product.
All manufactures	.....	$172,129,398
Based upon products of mines or quarries:		
Chemicals and allied products	$693,593	
Clay, glass, and stone products	1,810,335	
Iron and steel and their products	3,083,621	
Metals and metal products, other than iron and steel	26,696,884	
Miscellaneous industries	4,775,715	
		37,060,148
All other	.....	135,069,250

The average number of wage-earners in Kansas engaged in manufacturing, as reported at the Twelfth Census, was 35,193, and the wages paid amounted to $16,317,689. In 1902 the average number of wage-earners reported as engaged in mining was 8,726, and the wages paid amounted to $5,680,593. The two industries together therefore gave employment to an average of 43,919 wage-earners during the year and paid $21,998,282 in wages. Manufactures, therefore, gave employment to 80.1 per cent of the wage-earners and paid 74.2 per cent of the wages, while mines and quarries furnished employment to but 19.9 per cent of the wage-earners and paid 25.8 per cent of the wages.

Table 3 shows the value of the annual production of the leading minerals of the state from 1890 to 1902.

[1] Mineral Resources of Kansas, 1897, page 6.

TABLE 3.—VALUE OF ANNUAL PRODUCTION OF PRINCIPAL MINERALS: 1890 TO 1902.

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Natural gas.	Lead and zinc.[1]	Limestones and dolomites.	Petroleum.	Sandstones and quartzites.	Cement.	Gypsum.
1890	$2,947,517	$12,000	$674,701	$478,822	(2)	$149,289	[3] $122,500	$72,457

[1] Statistics for 1890 to 1901, inclusive, from "Mineral Resources of Kansas," 1900 and 1901.
[2] Not separately reported.
[3] Includes production from Missouri.
[4] Includes production from Nebraska and Texas in 1897, and Missouri and South Dakota in 1902.
[5] Includes production from Iowa and Texas.
[6] Census figures, except for cement and gypsum.

Coal.—The Coal Measures of Kansas are in the eastern part of the state and cover about 20,000 square miles, of which 15,000 square miles are rated as productive. Of this area, however, only a small proportion is actually producing at this time.[1] The Kansas coal fields are a part of the Western field, which also includes the bituminous coal deposits of Missouri, Nebraska, Arkansas, Indian Territory, and Texas. The coals in the state occur in various shale beds, occupying all positions from the Cherokee shales at the base to the Osage shales more than 2,000 feet higher.[2]

Coal was first mined in the state in southeastern Cherokee county in 1866 by the early settlers of that locality. The coal beds then operated are now entirely abandoned as they were in the thinner and lower veins. Some years later the heavy beds of coal now so extensively mined in Cherokee and Crawford counties were discovered.[3]

The following table, compiled from the reports of the United States Geological Survey, "Mineral Resources of the United States," 1902, shows the annual production of coal in Kansas since 1869:

TABLE 4.—*Annual production of coal, bituminous: 1869 to 1902.*

1884	1,100,000	1901	4,900,528
1885	1,212,057	1902	5,266,065

[1] The University Geological Survey of Kansas, 1898, Vol. III, page 117.
[2] Ibid., page 140.
[3] Mineral Resources of Kansas, 1897, page 36.

The 175 coal mines operating in 1902 were located in Atchison, Bourbon, Cherokee, Cloud, Coffey, Crawford, Franklin, Jewell, Labette, Leavenworth, Linn, Osage, and Republic counties. The total output of these mines for that year was 5,266,065 tons, of which Crawford county produced 2,881,274, and Cherokee county 1,849,896.

Natural gas.—The area throughout which gas has been found in greater or less quantities is in the southeastern part of the state, and embraces the counties of Miami, Allen, Neosho, Crawford, Wilson, Montgomery, and Labette. It is found in the sandstones and the more porous beds of the Cherokee shales, which are at the base of the Kansas Coal Measures.[4]

Though gas had been found in prospecting for oil, and had been noticed escaping from springs even as early as 1864,[5] it was not until the completion of the "Acres well" at Iola, Allen county, in 1873 that the development of this industry really began.[6] In 1882 for the first time what could really be called a gas well was struck in Miami county, at Paola.[5] In 1893 a good well was found in Allen county. In 1899 gas was successfully applied to the reduction of zinc ore, and it also began to be used for lighting in many of the large towns in southeastern Kansas, and in the manufacture of brick and hydraulic cement.[4]

The value of the natural gas produced by the 414 wells flowing in 1902 was $824,431, an increase of $165,258, or 25.1 per cent, over 1901.

Lead and zinc ores.—These ores are at present mined only in the extreme southeastern corner of Cherokee county. All the lead and zinc ores shipped from Kansas have been mined in this area, scarcely equal to four miles square.[7]

The lead and zinc ores of southeastern Kansas, or

[4] United States Geological Survey, "Mineral Resources of the United States," 1902, page 649.

[7] Ibid., page 23.

Galena district, occur in the Mississippian or Subcarboniferous limestone formation, which has a wide exposure in southwest Missouri, northwest Arkansas, and southeast Kansas.[1]

The first discovery of lead ore was made in Cherokee county in April, 1876, although similar mines had been operated for several years at Joplin and Granby and adjacent points in Missouri. In the spring of 1877 a large body of pure lead ore was discovered. Great excitement ensued, and the narrow Short creek valley was soon a busy scene of activity. Two rival town companies came upon the scene, one of which, obtaining control of considerable land on the south side of the creek, named its town Galena, and the other, having control of the north side, called its town Empire City. At first everything was confusion, no records of the output of ore being made, but after a time order was established.[2] The total value of the output of the products of the mines of Galena-Empire City, at the mines, from 1876 to 1897, inclusive, has been estimated at from $25,000,000 to $26,000,000.[3]

The following table shows the quantity of lead and zinc ores mined in Cherokee county, Kansas, from 1886 to 1902, the figures, except for 1902, being compiled from Table IX of the Annual Bulletin on Mineral Resources of Kansas for 1897:

TABLE 5.—*Production of lead and zinc ores: 1886 to 1902.*

[Mineral Resources of Kansas, 1900 and 1901.]

YEAR.	Lead ore (short tons).	Zinc ore (short tons).	YEAR.	Lead ore (short tons).	Zinc ore (short tons).
1886	2,962	31,768	1895	12,538	41,232
1887	3,073	32,795	1896	14,062	62,232
1888	2,624	33,391	1897	15,135	59,451

1893	5,140	25,028	1902[1]	3,468	21,642
1894	5,817	28,670			

[1] Census figures.

Limestones and dolomites.—The limestones of the state quarried at present are, almost without exception, of the Carboniferous or Permian age and occur only in relatively thin beds, varying in thickness from a few inches to 8 or 10 feet. They are, as a rule, light in color, soft and porous, and incapable of receiving a polish that would fit them for any form of ornamental work.[4]

Of the 115 quarries operating in 1902 only 15 had a production exceeding $10,000 in value and but 1 over $100,000. Marion county led all other counties of the state in value of production, and Franklin was second.

Petroleum.—The existence of oil springs in Miami and Wyandotte counties had been learned by the earliest settlers of the state from the Indians. While wells were drilled in the early sixties near Paola, in Miami county, practically all prospecting ceased until after the Civil War. The years from about 1871 or 1872 to 1890 constitute a second distinct period in the development of the oil wells of the state. During this period wells were drilled in Miami and Allen counties. It was not, however, until the introduction of larger capital and better methods subsequent to 1890 that the real development of petroleum began in the state.[5]

The present productive petroleum field of Kansas is in the counties of Neosho, Allen, Chautauqua, Montgomery, and Woodson. Of these Neosho county ranks first and Allen county second in point of production.[6]

The following table shows the annual production of petroleum in Kansas since 1889. It is compiled from the reports of the United States Geological Survey:

TABLE 6.—*Annual production of petroleum: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Barrels.	YEAR.	Barrels.
1889	500	1896	113,571
1890	1,200	1897	81,098
1891	1,400	1898	71,980
1892	(1)	1899	69,700
1893	18,000	1900	74,714
1894	40,000	1901	179,151
1895	44,430	1902	331,749

[1] Not reported.

Sandstones and quartzites.—Sandstones are said to occur in several counties in the southwestern part of Kansas, but few if any of these are of such a quality as to acquire other than a local market.[7]

The value of the output of the 19 quarries operated in 1902 was $105,509. Of this amount Bourbon and Phillips counties alone supplied $87,260, or 82.7 per cent. Elk, Labette, Montgomery, Neosho, Pawnee, Wilson, and Woodson counties also produced some sandstone.

All other minerals.—Natural rock cement was first manufactured in the state in 1868 at Fort Scott, Bourbon county, and has since been produced only in that locality.[8] In 1902 there were two plants producing natural rock cement located at Fort Scott, only one of which is

included in the census of mines and quarries, as the other purchased all the raw materials it used. The single Portland cement plant in the state, at Iola, in Allen county, began operations in 1900.[1] The statistics for the two plants embraced in the scope of the inquiry are included in "all other minerals" to avoid the disclosure of individual operations.

The gypsum deposits of the state early attracted the attention of geologists and prospectors, the first mention of them being made in 1864.[2] The deposits of gypsum near Blue Rapids, in Marshall county, were the first worked, the first mill being built in 1875.[3] Kansas is one of the leading states in the production of plaster of Paris and its practically inexhaustible deposits of gypsum will long be a source of supply.[4]

KENTUCKY.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells of the state of Kentucky for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Limestones and dolomites.	Natural gas.	Petroleum.	Fluorspar.	Sandstones and quartzites.	All other minerals.[1]
Number of mines, quarries, and wells	1,142	523	70	117	392	14	9	17
Number of operators	665	503	69	19	39	10	9	16
Salaried officials, clerks, etc.:								
Number	854	593	68	32	63	31	16	51
Salaries	$666,360	$476,508	$48,405	$34,250	$44,376	$21,107	$10,270	$31,444
Wage-earners:								
Average number	10,654	9,077	774	50	79	193	166	315
Wages	$5,193,792	$4,522,207	$319,700	$27,560	$69,189	$79,107	$63,589	$112,440
Contract work	$224,923	$10,668	$900	$9,297	$194,462	$300	.....	$9,296
Miscellaneous expenses	$600,613	$285,792	$14,443	$112,794	$147,295	$22,328	$928	$17,033
Cost of supplies and materials	$1,207,771	$743,313	$54,809	$37,197	$227,822	$13,952	$10,165	$120,513
Value of products	$8,533,423	$6,666,967	$593,747	$365,611	$172,837	$143,410	$128,470	$462,381

[1] Includes operators as follows: Asphaltum and bituminous rock, 5; clay, 5; cement 1 (2 mines); iron ore, 3; lead and zinc ore, 1; oilstones, whetstones, and scythestones, 1.

With extensive coal deposits in both the eastern and western parts of the state, Kentucky ranks eighth among the coal producing states. In limestones and sandstones fit for structural, architectural, and sculptural purposes the state takes high rank. It has excellent iron ores, extensive deposits of superior clays, abundant stores of Chester marls, and notable deposits of fluorspar, carrying lead and zinc. The state also possesses large fields of natural gas and petroleum, and much asphalt rock. It has in abundance the raw materials for the manufacture of both natural-rock and Portland cement.[1]

In addition to the productive properties shown in Table 1, 58 operators reported active mines, quarries, and wells, but no production, in 1902, the work being confined to the development of the properties. These operators employed on an average 33 wage-earners and paid $25,693 in wages during the year. The salaried officials, clerks, etc., received $23,481; the contract work amounted to $185,733; the miscellaneous expenses to $22,857; and the cost of supplies and materials to $67,620.

The value of the products of the manufacturing industries of Kentucky, based primarily upon minerals mined and quarried, and also the value of all manufactured products of the state as reported at the census of 1900, is shown in Table 2.

[1] Report of the Inspector of Mines of Kentucky, 1901–2, page 299.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$154,166,365
Based upon products of mines or quarries:		
Chemicals and allied products	$698,030	
Clay, glass, and stone products	3,098,521	
Iron and steel and their products	12,232,657	
Metals and metal products, other than iron and steel	2,909,676	
Miscellaneous industries	6,265,904	
		25,204,788
All other		128,961,577

The value of the products of manufactures, based primarily upon minerals mined and quarried, as shown by the foregoing table, was $25,204,788, or 16.3 per cent of the total value for all manufactures in the state. The total value of the output of the mines, quarries, and wells of Kentucky, in 1902, was $8,533,423, or 5.5 per cent of the total value of product for all manufacturing and mining industries in the state.

The manufacturing industries of Kentucky were reported at the census of 1900 as employing on an average during that year 62,962 wage-earners, and as paying $22,434,185 in wages. The operators of the mines, quarries, and wells of the state reported that they gave employment to an average of 10,654 wage-earners during 1902, and paid $5,193,792 in wages. The two industries combined, therefore, gave employment to

73,616 wage-earners and paid $27,627,977 in wages. Manufactures, therefore, furnished employment to 85.5 per cent of the wage-earners and paid 81.2 per cent of the wages, while mining employed 14.5 per cent of the wage-earners and paid 18.8 per cent of the wages.

The following table shows the value of the annual production of the leading minerals of the state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Limestones and dolomites.	Natural gas.	Petroleum.	Fluorspar.	Sandstones and quartzites.

[1] Not shown separately.
[2] Includes production from Illinois.
[3] Includes production from Tennessee.
[4] Census figures.

Coal.—There are two distinct coal fields in the state, the eastern, a part of the great Appalachian field and the western, a part of the Illinois or Central field. The two fields have an aggregate in Kentucky of 15,680 square miles of coal bearing measures, of which 11,180 square miles are in the eastern field and 4,500 in the western field.[1] A large part of each field is productive, and each contains from nine to twelve workable seams above the conglomerate sandstone series that lie at the base of the coal measures.[1] The eastern field has also from two to six beds included in the conglomerate series.[1] In 51 of the 53 counties in which coal occurs, workable beds are found.[1]

The existence of coal in Kentucky was undoubtedly known as early as 1770[2] and it was being mined in a small way in the western field from 1830 to 1840.[3] From 1840 to 1850 considerable coal was shipped down the Ohio river from Union and Hancock counties.[3] From 1850 to 1870 the state still produced but a few thousand tons, but in the latter year coal mining began on an extensive scale.[3] The first recorded coal production from the state was reported at the census of 1870.

In 1902 the 523 productive coal mines, located in 47 counties, produced 6,766,984 short tons, valued at $6,666,967. The net increase in production over 1901 amounted to 1,296,998 tons.[4] Hopkins county in the western field, with an output of 1,555,084 tons, ranked first in 1902 among the coal producing counties of the state; Muhlenberg in the same field, second; and Whitley county in the eastern field, third. The entire output of western Kentucky amounted to 3,761,606 tons in 1902, and that of eastern Kentucky to 3,005,378 tons.[5]

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of coal in the state since 1870:

TABLE 4.—*Annual production of coal, bituminous: 1870 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.
1870	168,654	1887	1,933,185
1871	250,000	1888	2,570,000
1872	380,800	1889	2,399,755
1873	300,000	1890	2,701,496
1874	360,000	1891	2,916,069
1875	500,000	1892	3,025,313
1876	650,000	1893	3,007,179
1877	850,000	1894	3,111,192
1878	900,000	1895	3,357,770
1879	1,000,000	1896	3,333,478
1880	1,000,000	1897	3,602,097
1881	1,100,000	1898	3,887,908
1882	1,300,000	1899	4,607,255
1883	1,650,000	1900	5,328,964
1884	1,550,000	1901	5,469,986
1885	1,600,000	1902	6,766,984
1886	1,550,000		

Limestones and dolomites.—The most valuable of the oolitic limestones of the state are found in Litchfield, Grayson county, and Princeton, Caldwell county.[6] The oolitic character is marked in these stones, and while a perfect surface can not always be produced, owing to the breaking away of the minute, rounded grains, in the better qualities, sharp edges and smooth surfaces are said to be acquired as readily as on the well-known stone of Bedford, Indiana.[6] The Bowling Green oolite, of Warren county, is of especial value as a building stone.[7] Handsome examples of the Lower Carboniferous limestones are to be found on the Rockcastle and Cumberland rivers, in the southeastern part of the state.[8]

Of the 70 quarries which were productive in 1902, but 21 reported an output in excess of $10,000, and of the 24 counties in which these productive limestone quarries were located, only 2, Jefferson and Jessamine, had a production valued at $100,000 or over. Warren county, with a production valued at $74,154, of which $44,500 was for building purposes, ranked third. The value of the limestone quarried in the state in 1902 was $593,747, which exceeds the amount for 1901 by $394,180.

Natural gas.—That the presence of natural gas in the state was early known may be seen from the description of the "Burning Spring," in Clay county, by Dr. D. D. Owen, in his report on the state survey for 1854 and 1855.[1] The first well which produced gas in any considerable quantity was drilled in 1863 near Brandenburg, in Meade county. In 1872 the gas from this well was used in making salt.[2] The search for natural gas was stimulated by the discoveries in 1885–86 in Ohio and Indiana.

The principal gas area thus far developed is in Martin county, in the eastern part of the state. The output of the 117 wells which supplied gas in 1902 was valued at $365,611, an increase of $94,740 over 1901.

Petroleum.—The existence of petroleum in Kentucky was undoubtedly known to the earliest settlers through the Indians, but the first known historical facts date from 1818 or 1819, when petroleum flowed so freely from a well dug in Wayne county for salt that it was abandoned for brine. In 1829 the famous American well was bored in Cumberland county near Burksville.[3]

Although operations in the south central oil district of the state have been carried on in a comparatively small way for many years, it has only been quite recently that the quest for oil has been prosecuted with vigor.[4] In 1902 the 392 productive wells, located in Barren, Bath, Clinton, Knox, Morgan, Rowan, Wayne, and Webster counties, produced 248,950 barrels, valued at $172,837. Wayne and Bath counties are the largest petroleum producing counties in the state.

The following figures from the reports of the United States Geological Survey show the annual production of petroleum in Kentucky since the earliest record. The difference between the Census figures and those of the Survey is caused by the fact that the former represent the petroleum produced and the latter the product marketed.

TABLE 5.—*Annual production of petroleum: 1882 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Barrels.[1]	YEAR.	Barrels.[1]
1882[2]	160,933	1893	3,000
1883	4,755	1894	1,500
1884	4,148	1895	1,500
1885	5,164	1896	1,680

1892	6,500		

[1] Includes production from Tennessee.
[2] Includes production previous to 1883.

Fluorspar.—This mineral is found in Crittenden, Livingston, and Caldwell counties associated with lead and zinc. The veins bearing fluorspar occupy fissures in the Carboniferous rocks, following the faultings that reach into the Coal Measures. The fluorite extends through the entire Genevieve group, excepting possibly the upper Chester.[5]

The ore deposits in the section of the state referred to have been known to settlers since early in the last century. The first attempt to mine them was made in Crittenden county by a company headed by President Andrew Jackson. Primitive attempts were also made at mining the ore deposits in Livingston county subsequent to the Civil War, and in 1878 nearly all mining in this district of western Kentucky had ceased. Up to 1878 lead only had been mined in this section, but the demand for fluorspar served to maintain a small interest in mining in the southern part of this district for a few years longer, when, owing to a slight drop in the value of this mineral and the cost of transportation, these mines became incapable of competing with the more favorably located mines on the other side of the Ohio river in Illinois.[6] Since 1898, however, interest in the fluorspar deposits of the state has been revived, and in 1902 Kentucky, with a production of 29,030 short tons of fluorspar from 14 mines in Crittenden, Fayette, and Livingston counties, was the largest producer of this mineral. The value of the state's output was $143,410.

Sandstones and quartzites.—One of the most valuable sandstones for structural purposes is quarried in Rowan county, and several of the sandstones of the Coal Measures are frequently quite good for bridge piers and foundations.[7] The 9 quarries productive in 1902 were located in Breathitt, Knox, Livingston, Rockcastle, Rowan, Warren, and Whitley counties, and had an output in that year valued at $128,470.

All other minerals.—Bitumens in Kentucky occur as impregnations of sandstones.[8] Fine examples are to be found in Breckinridge, Hardin, Grayson, and Logan counties, in western Kentucky, and in Carter county in the eastern part of the state.[9] In 1902 the state's production of bituminous sandstones amounted to 22,498 tons, valued at $68,704.

Fire clays of proved excellence are found in several counties of the eastern coal field and also in the western field. Pottery clays for ordinary use are abundant.[9] In 1902 Kentucky ranked fifteenth among the states in the value of its clay products, which amounted to $1,873,043.[10]

Natural cement rock was discovered in Kentucky in 1829, during the construction of the Louisville and

Portland canal. The manufacture of Louisville cement was commenced in that year at Shippingport, a small suburb of Louisville. The growth of the industry has not been rapid. As but one cement factory quarried its own material in 1902, no figures can be given without disclosing individual operations. The product of Indiana and Kentucky combined was 1,727,146 barrels, valued at $869,163.[1]

That the presence of iron ores in Kentucky was early known is proved by reference made to them in an article written by Thomas Jefferson before the close of the Revolution. The first iron furnace was built in the state in 1791, in Bath county.[2] For a number of years after 1800 the iron industry of the state made rapid progress, and from about 1825 to 1860 was the period of its greatest activity.[3] Although iron ore is found in many counties, both in the eastern and western coal fields of the state, comparatively little mining has been done,[4] and in 1902 iron ore was mined only in Bath, Lyon, and Trigg counties. The total production amounted to 71,006 tons, valued at $86,169. Both brown and red hematite were mined.

The lead and zinc ore deposits in Crittenden county were first mined by a company headed by President Andrew Jackson.[5] Other primitive attempts were made in Livingston county subsequent to the Civil War, but in 1878 nearly all mining in these counties had ceased, owing to cost of transportation and a drop in the price of the ores. These mines are at present being worked principally for the associated mineral fluorspar.[6] As only one operator reported any production of lead and zinc ores in 1902, no figures can be given.

The sandstone used by the single operator reporting oilstones and whetstones comes from Hardin county. No figures can be given without disclosing individual operations.

LOUISIANA.

Table 1 is a summary of the statistics for the productive mines and wells in the state of Louisiana for 1902.

TABLE 1.—*Summary: 1902.*

	All minerals.[1]
Number of mines and wells	8
Number of operators	3
Salaried officials, clerks, etc.:	
Number	8
Salaries	$7,533
Wage-earners:	
Average number	61
Wages	$34,444
Contract work	$105,558
Miscellaneous expenses	$25,820
Cost of supplies and materials	$7,354
Value of product	$279,327

[1] Includes operators as follows: Petroleum, 2 (7 wells); sulphur and pyrite, 1.

A few minerals of the state which were not produced in 1902, but which occur in sufficient quantities for commercial operations, call for mention. Among them are the sandstones of the hills of the northern part of the state and along the Grand Gulf. Only the latter, however, are of economic value, and these have been quarried extensively for riprap, jetty work, and railroad ballast. Limestones, which occur in beds of limited extent and as concretions, are also found in the state. The outcroppings have been used to some extent for lime, and the concretions have been used for the same purpose and also for road material and for cement.[1] Lignite, which has had only a limited local use for blacksmithing purposes, has been found. Gypsum occurs in several places, especially along the Ouachita river and in association with the sulphur deposits near Lake Charles, the gypsum in these deposits being of exceptional purity.[2]

Development work of considerable importance was carried on during the year, the total expenditure being $92,442. This outlay was confined to well boring and other expense incident to the development of the oil industry.

Petroleum.—Dr. William M. Carpenter, in his Geological Survey of Louisiana (1839), makes the statement that "in the lowlands bordering on the Calcasieu river there are numerous springs of petroleum." It was while boring for petroleum in this region that the discovery of the great sulphur deposit was made. One of the wells sunk here yields a small quantity of petroleum, which some years ago was collected and barreled. Prospecting wells have also been sunk on Belle Isle and in other localities in the state.[2]

Early in 1901 development work was started near Jennings, Welsh, Lake Charles, Sulphur, and a few other places in adjoining parishes. The Jennings Oil Company, drilling in Arcadia parish, 87 miles east of Beaumont, Tex., and about 190 miles west of New Orleans, on the line of the Southern Pacific Railroad, succeeded in finding oil in paying quantities. The company now has two good wells each producing from 2,000 to 2,500 barrels each per day. The Southern Oil Company early in 1902 completed a good well about 100 feet from the Jennings well No. 1, and both companies are making extensive preparations for handling their output.[3]

Sulphur.—There is a very large deposit of this mineral about 13 miles from Lake Charles in Calcasieu parish.[4] In 1868 the Louisiana Oil Company, while sinking a well at this point, struck at a depth of 443 feet a very extensive bed of almost pure sulphur, the analysis showing 99.93 per cent. During 1869 and 1870 other borings showed the average thickness of the deposit to be about 100 feet. Numerous attempts have since been made to exploit it, but the depth of the deposit below the surface and the beds of water-bearing sands which overlie it render mining operations difficult. In 1895 operations were begun with the Frash system, invented by Mr. Herman Frash, of Cleveland, Ohio, and by the use of this method a considerable product was taken from the deposit. The principle of the "air lift" pump was applied in 1896, and by this means a product of 265 tons a day was secured. The production from the mines in 1895 was about 800 tons; in 1896, 4,200 tons; and in 1897, 1,000 tons. Shortly afterwards the mines were closed, as their operation under the adverse conditions was too expensive to leave a reasonable margin of profit,[5] but work of a developing and experimental character ensued for some years, during which period the details of a chemical process for recovering the sulphur were being worked out. Operations, under the new method of mining, were resumed in 1900, and the mine has been a consistent producer since that time.

MAINE.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Maine for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Siliceous crystalline rocks.	Limestones and dolomites.	Slate.	All other minerals.[1]
Number of mines or quarries	135	110	11	7	7
Number of operators	141	103	11	7	20
Salaried officials, clerks, etc.:					
Number	208	163	16	22	7
Salaries	$193,814	$158,516	$13,236	$16,999	$5,063
Wage-earners:					
Average number	3,684	2,832	591	217	44
Wages	$2,284,789	$1,867,200	$288,512	$110,818	$18,259
Miscellaneous expenses	$121,556	$66,413	$37,613	$13,496	$4,034
Cost of supplies and materials	$476,964	$217,548	$226,694	$27,329	$5,393
Value of product	$3,656,134	$2,659,450	$745,132	$206,558	$44,994

[1] Includes operators as follows: Feldspar, 5; flint (operator reported under feldspar); mica, 2; precious stones, 13 (no mines).

As shown in the above table, quarrying is the chief mineral occupation in Maine. The value of siliceous crystalline rocks quarried during the year represents 72.7 per cent of the entire mineral production in the state, and limestone and slate are second and third, respectively, in value of production.

A number of minerals occur, for which no production was reported during 1902, although they were previously mined to a considerable extent. Barytes occurs sparingly in Hancock county. Clay has been mined to some extent, and beds of copper in Washington and Hancock counties have been worked with considerable success. Gold alloyed with platinum has been placer mined in Franklin county; it also occurs with metallic bismuth in Hancock county. Infusorial earth and tripoli are found in Hancock county, in pond bottoms near the coast. Iron ores are found in Aroostook, Washington, Piscataquis, Hancock, Knox, Cumberland, and Oxford counties. Graphite and lead occur in many localities throughout the state. Lead is charged with silver to such an extent that it has been said that "systematic mining might pay" in the districts where it occurs. Manganese is found in Knox, Hancock, Piscataquis, York, and Aroostook counties; marl occurs in the northern part of the state; and ocher may be obtained in Androscoggin and Cumberland counties. Molybdenum sulphide is found in Washington and Hancock counties and pyrite occurs in many localities, but chiefly in Hancock county. Sandstone, silica sand, native silver, talc and soapstone, and zinc blende are other minerals not mined, though found here and there through the state.[1]

[1] United States Geological Survey, "Mineral Resources of the United States," 1887, pages 736 to 739.

Table 2 presents the total value of the products for all manufacturing industries in 1900 together with the totals for those based upon the product of mines or quarries.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$127,361,485
Based upon products of mines or quarries:		
Chemicals and allied products	$143,631	
Clay, glass, and stone products	4,440,993	
Iron and steel and their products	3,869,968	
Metals and metal products, other than iron and steel	912,704	
Miscellaneous industries	4,891,144	
		14,258,440
All other		113,103,045

As shown in the above table, manufactures based primarily upon the products of mines and quarries constitute 11.2 per cent of the total product of all manufactures reported for the state at the census of 1900. The product reported during 1902 by the mines and quarries in the state is valued at $3,656,134, which amount is only 2.8 per cent of the combined value of the products of the manufacturing and mining industries, while manufactures represent 97.2 per cent of this total.

During the census year of 1900 the manufacturing industries of Maine gave employment to an average number of 74,816 wage-earners, who received $28,527,849 in wages. The operators of the mines and quarries in 1902 employed an average of 3,684 wage-earners, and paid $2,284,789 in wages. The combined industries therefore employed 78,500 wage-earners, who received $30,812,638 in wages. Manufacturing gave employ-

ment to 95.3 per cent of the wage-earners and paid 92.6 per cent of the wages, while mines and quarries gave employment to 4.7 per cent of the wage-earners and paid 7.4 per cent of the wages.

The annual production of siliceous crystalline rocks, limestones and dolomites, and slate is given in Table 3 as compiled from the reports of the United States Geological Survey.

TABLE 3.—*Annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Siliceous crystalline rocks.	Limestones and dolomites.	Slate.
1890	$2,225,839	$1,523,499	$219,500
1891	2,200,000	1,200,000	250,000
1892	2,300,000	1,600,000	250,000
1893	1,274,954	1,175,000	139,200
1894	1,551,036	810,089	146,838
1895	1,400,000	700,000	140,154
1896	1,195,491	608,077	124,086
1897	1,115,327	742,877	201,117
1898	1,032,621	1,283,468	199,287
1899	1,321,082	1,028,375	181,766
1900	1,568,573	691,312	177,342
1901	2,703,116	715,272	202,325
1902[1]	2,659,450	745,132	206,558

[1] Census figures.

The above table shows that the production of siliceous crystalline rocks during 1901 was the greatest of any year during the decade, and that the production for 1902 was but slightly less. The production of limestones during 1902 was less than half that reported in 1890, although an increase is shown over both 1901 and 1900. The production of slate in 1902 was greater than for any year since 1892. In that year and in 1891 the maximum production for the thirteen years was reported.

Siliceous crystalline rocks.—The state of Maine, during 1901, held first rank as a producer of granite in the United States, but in 1902 it was second to Massachusetts. The production during 1902 was valued at $2,659,450, of which amount $1,921,020 was the value of stone utilized for building purposes. The stone converted into paving blocks was valued at $354,530; and that for monumental purposes at $208,141. Lesser amounts for stone utilized as curbing, flagging, riprap, rubble, crushed stone, and for other purposes were reported, the total being $175,759.

The rocky coast of Maine and adjacent islands furnish immense quantities of granite rock of an excellent color and quality, and the convenient location of the deposits to navigable waters appealed long ago to the enterprising New England business men. The first successful attempt at quarrying in Maine is said to have been in 1825; and in 1836 and 1837 there was considerable activity in the stone industry of the state. In 1837 thirty acts of incorporation were granted by the legislature to quarry companies.[1]

[1] Stones for Building and Decoration, by George P. Merrill, pages 3 to 5.

The Vinalhaven quarries on Penobscot bay were first operated in 1850, and the product being well adapted for ornamental and building purposes has been extensively used all over the country. The quarries at Mt. Waldo, near Frankfort, were opened in 1853. The stone has been largely used in the building of forts on the coast, as well as for ornamental and other purposes, and has been shipped as far south as Mobile and New Orleans. In this section of the state are found some of the most extensive quarries in operation in the country. The granite for the United States Treasury building at Washington, D. C., was obtained from Dix island in Knox county. The Hallowell quarries in Kennebec county furnish one of the best working granites, and many prominent buildings and monuments have been constructed wholly or in part of this stone. Among these may be mentioned the New York state capitol at Albany, N. Y., the Maine state capitol at Augusta, the old Tombs prison, New York city, and the statue on the Pilgrims Monument at Plymouth, Mass. Many other localities are rich in deposits of siliceous crystalline rocks, and quarrying operations were reported during 1902 in 13 of the 16 counties of the state.[2]

Limestones and dolomites.—Limestone is abundant in Maine, especially in the southeastern part of the state. The entire product during 1902, reported from Knox county, was valued at $745,132, and was practically all burned into lime.[3] This stone is not commonly utilized for building, as its colors, blue and blue-black, veined with white, are poorly adapted for such purpose.[4]

The lime industry in Knox county dates back to the year 1733, when Samuel Waldo experimented upon the limestone of this locality, and, finding it of satisfactory quality, erected a kiln and prepared lime for the Boston market. The first cargo of lime shipped to New York was in 1823, and sold at $2 per cask. In 1888 the market price was about 97 cents per cask,[5] while in 1902 the price is reported at from 60 to 75 cents per barrel, when prepared for shipment.

Slate.—The production of slate is chiefly in Piscataquis county, although a small quantity has been reported near Waterville, in Kennebec county. The value of slate quarried in the state during 1902 was $206,558. Of the total quantity quarried, 26,468 squares, valued at $143,832, were used for roofing.[6]

Slate was discovered by Welsh farmers near Brownville, and a quarry in this vicinity was opened by A. H. Morrill as early as 1846. In 1870 slate quarrying

[2] Stones for Building and Decoration, pages 56 to 66.

began at Monson,[1] and these quarries are still the most important in the state. In color the slates are distinctively slate-blue to blue-black, resembling those of Pennsylvania. The best grades are generally of smooth homogeneous texture, strong, durable, handsome, and holding a uniform color on the roof.[2]

All other minerals.—The feldspar obtained in Maine is considered the best in the United States. Feldspar quarrying near Auburn in Androscoggin county began in 1896. The spar occurs in pockets rather than in a continuous vein; the product obtained is pure and remarkably white.[3] The occurrence of this mineral is noted at other localities, quarrying being reported at Hebron, in Oxford county, and near Georgetown and Topsham, in Sagadahoc county, during 1902. The production of a considerable quantity of flint is reported with that of feldspar in Androscoggin and Sagadahoc counties.

No mining operations are reported for precious stones in the state of Maine, but a number of important finds were reported to dealers. Tourmaline and beryl of a considerable value were discovered during 1902 in Oxford county. In the same county two mica mines were reported during the year, but separate statistics can not be given without disclosing the operations of individual establishments.

MARYLAND.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Maryland for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Siliceous crystalline rocks.	Limestones and dolomites.	Cement.	Slate.	Flint.	Iron ore.	Sandstones and quartzites.	All other minerals.[1]
Number of mines or quarries	232	44	17	102	4	6	6	29	5	19
Number of operators	209	30	13	100	4	6	5	28	5	18
Salaried officials, clerks, etc.:										
Number	398	210	65	53	22	10	14	5	2	17
Salaries	$465,665	$315,791	$67,925	$31,289	$17,227	$4,520	$11,080	$1,910	$1,148	$14,775
Wage-earners:										
Average number	6,826	4,936	817	430	170	145	65	76	12	175
Wages	$4,323,939	$3,468,117	$435,372	$159,793	$74,677	$72,179	$21,383	$22,349	$5,394	$64,675
Contract work	$8,499	$8,499								
Miscellaneous expenses	$443,170	$312,198	$43,856	$20,841	$17,914	$5,523	$9,572	$12,314	$51	$20,901
Cost of supplies and materials	$859,755	$510,092	$107,435	$135,560	$51,879	$18,078	$8,627	$2,639	$1,152	$24,293
Value of product	$7,313,712	$5,579,869	$758,203	$453,030	$150,680	$118,084	$55,551	$46,911	$15,405	$134,979

[1] Includes operators as follows: Clay, 6; feldspar, 2 (3 mines); gold and silver, 1; infusorial earth, tripoli, and pumice, 1; marble, 2; mineral pigments, crude, 4; talc and soapstone, 2.

Coal mining is by far the most important mineral industry in the state, which ranked eleventh among the states in 1902 in the output of this mineral. The Cumberland coal field, which has been sending its high-grade steam coal into the market for nearly three-quarters of a century, and from which the entire coal product of Maryland is obtained, is the nearest to tide water of all the bituminous coal fields which supply the great coal markets of the northern Atlantic seaboard. The coal beds of the state are so situated as to yield a practically unlimited increase in production should the trade of the seaboard markets demand it.[1] Quarrying, with a product distributed, in the order of importance, among siliceous crystalline rocks, limestones and dolomites, and slate, constitutes also an important branch of the mineral industry of the state.

The minerals of known occurrence in the state, that were not commercially produced in 1902, are as follows: Asbestos, chrome, cobalt, copper ore, lead ores, graphite, gypsum, lignite, manganese, marl, molybdenum, nickel ores, quartz, serpentine, and zinc ores.

Development work during the year was confined to gold and silver and copper ore, with no return in product.

The relative importance of certain manufacturing industries of the state closely allied to, or based upon, the mining industry, since they use as their raw material the product of the mine and quarry, is shown in Table 2, as indicated by the value of their product.

[1] United States Geological Survey, Sixteenth Annual Report, page 132 ff.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$242,552,990
Based upon products of mines or quarries:		
Chemicals and allied products	$11,646,136	
Clay, glass, and stone products	5,110,578	
Iron and steel and their products	20,248,863	
Metals and metal products, other than iron and steel	33,174,693	
Miscellaneous industries	10,118,618	
		80,298,888
All other		162,254,102

The total value of the products of the manufacturing industries based on mining, as shown by Table 2, was $80,298,888, or 33.1 per cent of the total value of the product of all manufacturing industries in the state in 1900. During the same year there were employed in all branches of manufacture in the state 108,325 wage-earners, who received $38,748,551 in wages. In 1902 there were employed in the mines and quarries of the state 6,826 wage-earners, who received $4,323,939 in wages. Of the combined figures for these two branches of industry, therefore, 94.1 per cent of the wage-earners, receiving 89.9 per cent of the wages, were employed in manufacturing, while 5.9 per cent of the wage-earners, receiving 10.1 per cent of the wages, were employed in mining.

Table 3 shows the value of the annual production of the principal minerals of the state from 1890 to 1902.

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

Coal.—Some authorities place the discovery of coal in Maryland in the year 1801 at a point 6 miles northeast of Baltimore, and Benjamin Henfrey as the discoverer.[1] The first well authenticated discovery was made in 1804, at a point in Allegany county near the present site of Frostburg, by a Mr. Riser.[2] Various openings were made in the deposits from time to time, and they were worked on a small scale, chiefly for local use, for more than a quarter of a century. In 1830 the industry reached its second stage of development, when the first eastern shipment of coal was made from the old Neff mine. This first cargo was loaded at Cumberland and boated down the Potomac to Washington. For a decade or more the output of coal was confined to a very limited market, on account of the expensive and ineffective transportation facilities. The exceptional quality of Cumberland coal soon began to attract the attention of users at greater distances, and its mining, from the first shipment over the Baltimore and Ohio Railroad, in 1842, developed rapidly, and before long became the most important factor in the mineral industry of the state. The total shipments from the Cumberland region in this first year were 1,708 long tons. The annual output grew in the decade ending in 1852 to 334,178 long tons, and in 1860 it had increased to 788,909 long tons. During the earlier years of the Civil War the industry suffered a slight decline, but recovered in 1863, and at the end of the next decade, in 1872, the output exceeded 2,000,000 tons. The output remained at about this figure during the next ten years. The general industrial activity of the decade from 1882 to 1892 was shared by the coal mining industry in the Cumberland region, and the production again increased rapidly, reaching its maximum in 1891, when the state's output was 3,831,251 short tons.[3]

Table 4 shows the annual coal production, in short tons, from 1842 to 1902:

1862	346,201				

The coal deposits of the state are confined to western Allegany and Garrett counties and form a part of a long, narrow, detached coal field, lying on the extreme fringe of the great Appalachian coal basin. This wedge shaped strip, beginning just north of the Pennsylvania line and extending across Maryland into West Virginia, is known as the "Cumberland field." In some respects it is one of the most important in the United States.[3]

Maryland's share of these economic coal deposits is known by various names, among which are the "Frostburg basin" and the "Georges Creek basin." It is situated in an elevated trough to the west of the town of Cumberland, between two parallel ridges, known as Davis and Savage mountains, which are less than 4 miles apart. There are five workable coal seams, ranging in thickness from 14 feet in the "Big Vein" down to 3 feet in the vein of the Bayou formation.[4] The bulk of the state's coal production is mined in Allegany county, though the number and extent of workable seams in Garrett county afford much promise for future exploitation there.

The state's coal product comprises two distinct classes or varieties. That known as bituminous contains a high proportion of volatile gases and less than 70 per cent of carbon, and is especially valuable for the manufacture of coke and gas. This variety is not extensively mined at present. The other class, known as semi-bituminous, has no superior as a steam coal, and constitutes the bulk of the output of the mines of the state.

Siliceous crystalline rocks.—Granite quarrying in the state began in Cecil county in 1816.[5] During 1816 and 1817 a bridge was built across the Susquehanna river at the present site of Port Deposit. Stone for the construction of abutments was quarried near the present site of the extensive McClenahan quarries in Cecil county. The exceptional qualities of the stone soon came to be recognized, and after the completion of the bridge, further and extensive exploitation of the granite

[4] Geological Survey of Maryland, Vol. I, page 219 ff.
[5] Geological Survey of Maryland, Cecil county, page 196 ff.

in the vicinity was carried on. A very important industry has flourished there since. The Port Deposit granite is of a gneissoid character, light bluish gray in color, and eminently strong and durable.[1]

The occurrence of granite and gneissoid rocks in the state is confined within the area known as the Piedmont plateau, a broad belt extending from Cecil and Harford counties on the northeast to Montgomery county and the Potomac river on the southwest. Within this area is an abundance of excellent building material, though quarry development has not yet been rapid. In the vicinity of Ellicott City occurs a dark gray granite which is rendered porphyritic by the presence of ill-defined crystals of pink feldspar. This has been quarried since an early period in the state's history and has been extensively used for building purposes, especially in Baltimore. One of the best granites in the state for most of the uses which granite serves occurs within a small area in the southwestern corner of Baltimore county, near Woodstock. This rock has been extensively quarried with few interruptions since 1832–33. Among the many important buildings in the construction of which it has been used as material are the Capitol, Patent Office, old Post Office, and Library of Congress in Washington.[2] The stone is of medium texture and of dark gray color. Another granite which is remarkably free from defects, and which is well adapted to monumental as well as to general structural purposes, is found near Guilford, in Howard county. This stone is of moderately fine and uniform grain and of a light gray color. Large quantities of dark gray gneiss for local use in rough building work is quarried in the immediate vicinity of Baltimore.[3]

Limestones and dolomites.—Of the carbonate of lime deposits in the state, the limestones, as distinguished from the marbles, occur generally throughout the western part, or the Appalachian region, and in the form of limestone conglomerate or "Potomac marble" in the Frederick valley.

The blue limestones are in demand locally for building purposes. On weathering, this stone changes its color rapidly. The limestone of the Frederick valley is known as "calico rock" or "Potomac marble" and was used for the columns in the construction of the old Hall of Representatives in Washington. A good exposure of this rock is at Washington Junction, and its occurrence extends northward along the base of the Catoctin mountains.[4] Buckeystown, in Frederick county; Cockeysville, in Baltimore county, and Baltimore have long been important points in the manufacture of lime.[5]

[4] Geological Survey of Maryland, Vol. I, page 209 ff.
[5] The United States Geological Survey, "Mineral Resources of the United States," 1887, page 533.

Cement.—The industry of hydraulic cement manufacture is one of considerable relative importance in the state. The greater part of the state's output comes from the limestones in the vicinity of Cumberland and Hancock and from the Shenandoah limestones of the Hagerstown valley near Sharpsburg. The cement produced is of excellent quality, and the demand for it extends beyond the state.[6] The following table shows the annual production of cement since 1890:

TABLE 5.—*Annual production of cement: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Barrels.	YEAR.	Barrels.
1890	223,209	1897	296,000

1892	[1] 252,092	1899	362,000
1893	[1] 231,590	1900	335,070
1894	[1] 279,000	1901	351,329
1895	[1] 242,000	1902	409,200
1896	[1] 271,500		

[1] Includes production from West Virginia.

Slate.—Since Revolutionary times the slate deposits of the Peach Bottom region in Harford county have been worked for a roofing material, and the exceptional quality of these slates is strongly evidenced by the fact that after a hundred years' exposure they show almost no change. The area in which they occur is a narrow zone beginning near Pylesville, on the Baltimore and Lehigh Railway, and running into York and Lancaster counties, Pennsylvania.[7]

Flint.—Maryland is a very important contributor to the aggregate output of flint and quartz, commercially known as flint in the United States. In 1902, 6 of the 19 active quarries in the United States were located within the state, and 49.2 per cent, or about one-half of the output of ground flint in the country came from these quarries. Important centers for the production of flint and quartz are Darlington and Conowingo.[8]

Iron ores.—The iron industry in Maryland, whose development began in the early days of the colonial period, was for more than a century one of the most important factors in the prosperity of the state. The first recorded notice taken of the iron ores of Maryland and Virginia by the early settlers was in 1608, when Capt. John Smith sent 2 barrels of iron ore specimens to England for examination. Nothing is known of the result of this examination. About one hundred years later the first recorded operations were inaugurated by some Welsh miners in the vicinity of Iron Hill and Elkton. The extent of these operations is not known, but in the development of the iron ores of this same region in the nineteenth century, "the miners employed in the ore pit on Iron Hill came upon one of the galleries made by the Welsh miners and

[6] Geological Survey of Maryland, Vol. I, page 213 ff.
[7] Ibid., page 211.
[8] United States Geological Survey, Seventeenth Annual Report, pages 838 and 846.

discovered a rude shovel and pick and a small tallow candle, the wick of which was made of flaxen yarn. The candle, though probably a century old, was in a good state of preservation, but the shovel and pick were so badly rusted that the former could be readily picked to pieces with the thumb and finger."[1]

The first iron works in Maryland were probably erected in Cecil county at the head of Chesapeake bay. It is probable, also, that the bloomery built at North East, on North East river, before 1716 formed the pioneer iron enterprise of that character. Scrivenor, in his "History of the Iron Trade," published in 1841, says that in 1718 Maryland and Virginia exported "3 tons and 7 cwt." of bar iron to England, and, since Virginia had no forges at that date, the shipment must have come from the works of Maryland.

The era of systematic iron production in the state was opened by the organization in 1722 of the Principio Company, which in that year began the construction of a furnace at the mouth of Principio creek. Shortly after the organization of the company Mr. John England, of Bristol, England, who proved to be one of the most intelligent, enterprising, and successful of the early American ironmasters, became its general manager. He built the first furnace and the first forge in the state. The enterprise grew rapidly and soon its production of iron had reached a scale of commercial importance. About 1725 Augustine and Lawrence Washington, the father and half-brother of the first President,[2] became interested in the company, which soon outranked all others in the manufacture of pig and bar iron from its three furnaces and two forges in Maryland and one furnace in Virginia. For fifty years it was the most important of colonial iron enterprises, contributing one-half to the total exports of pig iron from the colonies to England up to the Revolution.[3] The marked success of this company brought others into the field for the exploitation of the iron deposits of the state, and by 1761 the industry had attained a flourishing condition. This is indicated in a report made by the governor to the effect that there were 18 furnaces and 10 forges in the state which made 2,500 tons of pig iron a year.[4] During the middle and latter part of the eighteenth century and the early part of the nineteenth, the industry of iron manufacture spread to other sections of the state and many furnaces were built, but nearly all of these were later abandoned. One of the most notable of these was the Catoctin furnace at Frederick, which was built in 1774, and furnished guns and projectiles to the Continental Army during the Revolution.

In recent years several modern furnaces have been built in the vicinity of Baltimore. By far the largest of these is at Sparrows Point, which plant, however, uses only ores obtained from sources outside the state.

Since the discovery of extensive deposits of higher grade ores in other sections of the country, notably in Michigan, Pennsylvania, and Alabama, the industry of iron ore mining in the state has rapidly declined until now the great iron using industries of the state depend to only an inconsiderable extent upon local ores.[5]

Sandstones and quartzites.—The quarrying of sandstones and quartzites in the state has continued in a more or less systematic way from the building of the old Potomac canal around the Great Falls of the Potomac, in 1774, when Seneca sandstone was used in the construction of two locks, down to the present time. This red Seneca sandstone has long been highly regarded alike for its durability, for the ease with which it can be worked, and for its beautiful colors. It entered largely into the construction of the Smithsonian Institution at Washington. Other occurrences of sandstone that have been exploited, and for which there is a greater or less demand, are in Harford county in the Catoctin and Blue Ridge mountains, and in Allegany county.

All other minerals.—Another factor of the mineral wealth of Maryland is found in the clay deposits, which are widely distributed and in many cases possess characteristics that render them of exceptional economic importance.

The first plant constructed in the United States for the manufacture of fire brick was that built in 1841 at Mt. Savage in Allegany county. The main fire clay deposits of the state lie near the bottom of the Coal Measures, the beds ranging from 8 to 20 feet in thickness. Their exploitation has been a characteristic industry of the state for more than fifty years, and the brick made from them are considered the best in the country. The clay deposits of the state that are most extensively exploited at present are those comprised in the Columbia and Patapsco formations. The center of their manufacture into terra cotta work and pottery is Baltimore.[6] The kaolin deposits of Cecil county, which are a continuation of the Delaware deposits, have been extensively mined for use in the manufacture of white ware for many years.[7]

Feldspar occurs at a number of places in the state, but was produced commercially in 1902 from only three mines located in Baltimore, Cecil, and Harford counties.

The discovery of gold occurred in Maryland in 1849, near Sandy Spring, in Montgomery county, and most of the mines subsequently opened lie along the southern boundary of this county in the vicinity of the Great Falls of the Potomac. The known occurrences of gold in the state are confined to the Piedmont plateau, and are in quartz veins. Some very rich specimens have

[6] Ibid., page 214 ff.
[7] Maryland Geological Survey, Cecil county, page 211 ff.

been found in this region, but the deposits of the metal are not sufficiently even to render its mining profitable.[1]

Infusorial earth has been produced in greater quantities in Maryland than in any other state in the country. The deposits occur at the base of the Chesapeake formation, and in parts of Calvert and Charles counties attain a thickness of 30 or 40 feet. The beds have been extensively worked in the vicinity of the mouth of Lyon's creek on the Patuxent river and at Pope's creek on the Potomac.[2]

The industry of marble quarrying in the state dates probably from 1815, when material for use in the Washington Monument at Baltimore was taken from the deposits at Cockeysville in Baltimore county. This point continues to be the important marble producing center of the state. The 26-foot monoliths in the National Capitol were taken in 1859–61 from what is now known as the Beaver Dam quarry. Though there are numerous occurrences of marble deposits, those which have been developed sufficiently to demonstrate their economic importance are limited to what is known as the Green Spring valley, extending east and west at a distance of from 12 to 20 miles north of Baltimore. In this belt are located the two quarries mentioned. The stone is a white dolomite of medium texture, strong and durable. Small lenses of compact crystalline marble occur in Carroll and Frederick counties. Also at Texas occurs a coarsely crystalline white limestone, sometimes known as alum marble, which is extensively quarried, mainly for quicklime and flux, though it was used in constructing the lower 150 feet of the Washington Monument in Washington.[3]

Ores from which mineral paints are made are of quite common occurrence in the state and have been worked at many points. In former years large quantities were obtained from the brown ore deposits in Frederick county and also in Carroll and Harford counties. The Patapsco formation in Anne Arundel and Prince George counties carries easily worked deposits of a fine and highly ferruginous clay. This belt at present is the principal seat of the industry of mineral pigment production in the state.[2]

Soapstone occurs in several counties, especially Carroll, Harford, and Montgomery, where it has been mined at various times. The most extensive deposits are in Carroll county, in a northwesterly direction from Marriottsville.[4]

MASSACHUSETTS.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Massachusetts for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Siliceous crystalline rocks.	Sandstones and quartzites.	Limestones and dolomites.	Marble.	All other minerals.[1]
Number of mines or quarries	251	204	19	11	8	9
Number of operators	234	194	15	8	8	9
Salaried officials, clerks, etc.:						
Number	360	279	35	17	13	16
Salaries	$309,978	$248,512	$25,536	$12,606	$12,468	$10,856
Wage-earners:						
Average number	4,242	3,395	342	203	130	172
Wages	$2,525,405	$2,045,340	$222,977	$99,740	$72,730	$84,618
Contract work	$1,853					$1,853
Miscellaneous expenses	$273,791	$211,745	$35,440	$10,192	$7,837	$8,577
Cost of supplies and materials	$762,335	$509,702	$59,486	$133,609	$18,324	$41,214
Value of product	$4,671,855	$3,451,397	$487,366	$339,349	$165,489	$228,254

[1] Includes operators as follows: Asbestos, 1; clay, 1; corundum and emery, 1; feldspar (operator reported under flint); flint, 1; graphite, 1; infusorial earth, tripoli, and pumice, 1; iron ore, 1; sulphur and pyrite, 1; talc and soapstone, 1.

The principal mineral industry of Massachusetts is quarrying, and as shown in Table 1, the value of siliceous crystalline rocks quarried in 1902 represents 73.9 per cent, or nearly three-fourths of the entire mineral production of the state. Massachusetts granite was the first to be systematically produced in the United States, and the state continues to lead in that production.[1] Sandstone, limestone, and marble are also quarried in considerable quantities, and the statistics for these operations are given separately in the table.

Among the minerals listed in the group of "all other minerals" are two of great importance. More than half of the emery produced in the United States is mined by one operator in Massachusetts, and a large proportion of the sulphur and pyrite production is also contributed by this state. Although these are of great importance, the statistics can not be shown separately because to do so would disclose the reports of individual operators.

A number of minerals for which no commercial production was reported in 1902 are known to occur in the state. Among these the following may be mentioned: Barytes, which occurs chiefly as gangue, with lead and copper, in Hampshire and Franklin counties; a very hard anthracite coal in Bristol, Plymouth, and Norfolk counties, which can not be mined profitably; chalcopyrite found in pyrite vein in Franklin county;[2] fuller's earth and garnet found in Worcester county, and garnet also in Framingham, Middlesex county; native gold found in small quantities in Middlesex, Norfolk, and Plymouth counties; deposits of stone suitable for use as millstones or whetstones in Hampshire, Norfolk, and Berkshire counties; lead ore found in Essex, Hampshire, Middlesex, and Worcester counties; manganese in small beds in Hampshire, Berkshire, and Franklin counties; ocher in Berkshire and Worcester counties; amber, agate, amethyst, beryl, jasper, jade, smoky quartz, and topaz are precious stones that have been reported in the state; quartz sand found in Berkshire, Essex, and Franklin counties; quarries of slate for local use, operated in Worcester and Middlesex counties; sphalerite or zinc blende occurring with galena in Franklin and Hampshire counties and at the Newburyport lead mines in Essex county, where operations were carried on before 1878.[3]

The relative importance of manufacturing industries closely allied to, or based upon the mining industry, using as their raw material the product of the mine or quarry, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$1,035,198,989
Based upon products of mines or quarries:		
Chemicals and allied products	$6,091,402	
Clay, glass, and stone products	12,763,947	
Iron and steel and their products	97,735,863	
Metals and metal products, other than iron and steel	29,232,650	
Miscellaneous industries	51,107,117	
		196,930,979
All other		838,268,010

[1] Stones for Building and Decoration, by George P. Merrill, pages 2 and 3.

[2] The United States Geological Survey, "Mineral Resources of the United States," 1887, pages 742 to 744.

[3] The United States Geological Survey, "Mineral Resources of the United States," 1887, page 745.

From the foregoing table it will be seen that 19 per cent of the total manufactured product of the state was based primarily upon the products of mines and quarries. The total product of manufactures as reported at the census of 1900 was $1,035,198,989; there were employed 497,448 wage-earners, who received $228,240,442 in wages. The product of mines and quarries in the state during 1902 was valued at $4,671,855, and there were reported as engaged in this production 4,242 wage-earners, to whom was paid the sum of $2,525,405 in wages.

Therefore the value of the product of mines and quarries was but four-tenths of 1 per cent of the combined product of mineral and manufacturing industries, 99.6 per cent of the total being contributed by manufactures. There were engaged in mining and quarrying eight-tenths of 1 per cent of the total number of wage-earners, and these received 1.1 per cent of the total wages. The manufacturing industries employed 99.2 per cent of the total wage-earners, and paid 98.9 per cent of the total wages.

The following table shows the value of the annual production of the principal minerals of the state from 1890 to 1902, inclusive:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Siliceous crystalline rocks.	Sandstones and quartzites.	Limestones and dolomites.	Marble.
1890	$2,503,503	$649,097	$119,978	(1)
1891	2,600,000	400,000	100,000	(1)
1892	2,200,000	400,000	200,000	$100,000
1893	1,631,204	223,348	156,528	(1)
1894	1,995,830	160,231	195,982	(1)
1895	1,918,894	339,487	75,000	2,000
1896	1,656,973	304,361	118,622	83,904
1897	1,736,069	194,684	126,508	79,721
1898	1,650,508	91,287	174,822	38,210
1899	1,798,294	131,877	168,147	59,416
1900	1,698,605	153,427	209,359	130,735
1901	2,216,258	247,310	244,039	126,546
1902[2]	3,451,397	487,366	339,349	165,489

[1] Not reported. [2] Census figures.

The production of 1902, according to Table 3, increased over that of 1901 in all the industries presented. The production of siliceous crystalline rocks, as well as that of limestones and dolomites, during 1902 was greater than that reported during any year of the thirteen years shown in the table.

Siliceous crystalline rocks.—The Massachusetts production of siliceous crystalline rocks during 1902 was valued at $3,451,397, which is greater than the amount reported for any other state in the Union. Thirty-nine per cent of this value, or $1,347,214, was used for dressed stone for building and monumental work; 27.1 per cent, or $936,413, was for stone sold in the rough, and the remainder was for paving purposes, crushed stone, riprap, etc., in the order named.

In a strictly scientific sense, most of the siliceous crystalline rocks of Massachusetts are not granites, but granitites or gneisses.

The granitites differ from granite proper in the absence of white mica, while gneisses are crystalline rocks which possess a more or less well-marked banding, usually due to the arrangement of the micas in defined planes.[1]

Although granite bowlders were used in construction as early as 1650,[2] it was not until the early part of the nineteenth century that quarrying was prosecuted to any considerable extent in Massachusetts. In 1810 the Boston court-house, in 1814 the New South church, and in 1818–19 the first stone block in Boston were constructed of stone introduced by canal from Chelmsford, 30 miles distant. The quarries of Quincy, in Norfolk county, were opened about 1820, and the history of systematic siliceous crystalline rock quarrying in New England begins at this time.[3]

The stone obtained from this locality is coarse grained and very hard and in color generally a dark blue-gray. It is classed as a hornblende pyroxene, and although the brittle pyroxene makes the production of a perfect surface somewhat difficult, it is still used extensively for finished as well as for rough work. Its suitability for interior decoration may be seen in the polished stairways and pillars of the Philadelphia city buildings. The Quincy stone was first brought into prominence in 1825 through its use in the construction of the famous Bunker Hill Monument at Charlestown, and what is claimed to be one of the first railroads in the United States was built a distance of 3 miles from these granite quarries to the Neponset river in 1826.[4]

Probably the Gloucester quarries at Bay View, in Essex county, were the next to be worked, being opened in 1824. The rock obtained is hornblendic with considerable black mica or annite, coarse in texture, and greenish or gray in color. It is hard and tough, and being very durable, it is eminently suitable for building and ornamental work. A number of other quarrying localities were opened in Essex county, chiefly at Rockport in 1830. The stone quarried resembles the Gloucester type and may be obtained in massive blocks.[5] The stone quarried at Chester, Hampden county, is clear gray or bluish gray of medium shade; it is homogeneous and of fine, even grain.[6]

At Dedham, Norfolk county, there is produced an epidote granite of fine grain and light pink, tinged with green, in color, and at Brockton, Milford, and North Easton a light pink variety of coarse biotite is quarried.

The stone obtained at Milford, Worcester county, possesses a more or less plainly marked banding, which increases its beauty without any depreciation of its strength or usefulness. At Monson, Hampden county, a characteristic gneiss is quarried and in a number of

[6] United States Geological Survey, Eighteenth Annual Report, page 965.

other localities siliceous crystalline rocks may be found.[1] Quarrying operations have proved very successful in Massachusetts, as the largest deposits are adjacent to navigable water, which renders shipment convenient and comparatively inexpensive.

Sandstones and quartzites.—The sandstone and quartzite production of Massachusetts during 1902 was valued at $487,366. More than one-half of the amount quarried was used in roadmaking and the rest, with the exception of a small amount reported as rubble, was sold principally in the rough or dressed condition for building purposes. In the vicinity of East Longmeadow, Hampden county, are found the principal sandstone quarries, and some of the earliest quarrying operations have been reported in this locality. Sandstone of several colors, fine grained and of a massive type, is obtained, and is used chiefly for building purposes.[2] Geologically speaking, this sandstone locality is a northward continuation of the Connecticut brownstone deposit, extending into Massachusetts as far north as Northampton. This stone is of a Triassic variety and is soft and easily worked.[3]

A number of quarries in and about Boston, principally municipal in ownership, yield a so-called pudding stone; this is a rough and durable stone suitable for roadmaking, concrete, etc., but generally too coarse for ornamental work.[3] These conglomerates in Roxbury, Suffolk county, came into use about 1840, and have been utilized somewhat in building construction and for the rustic masonry work of the Boston system of parkways.

Limestones and dolomites.—Massachusetts limestones and dolomites are obtained entirely in Berkshire county; the production during 1902 was valued at $339,349. They occupy a belt along the Housatonic river and are of the same age as those of Rutland valley, Vt., to which stones they bear a close resemblance.[4]

Marble.—The production of marble in Massachusetts for 1902 was valued at $165,489 and quarrying operations were chiefly reported in Berkshire county. In composition the marble ranges from marble proper to dolomites, or to varieties carrying a high percentage of magnesium carbonate.[2] At Egremont quarries was obtained the marble for the Corinthian columns of Girard College in Philadelphia about 1835. In 1838 the Sheffield, and in 1852 the Lee quarries were opened. Stone from the latter was used in the extension of the Capitol at Washington, D. C. The marbles are all white or gray, of medium fine grained texture, and are better adapted for building than for decoration. They often contain white tremolite crystals which weather out on exposure, leaving the rock with a rough pitted surface, as may be noticed in the exterior walls of the Capitol, where this marble has been used.[5]

[5] Stones for Building and Decoration, page 215.

All other minerals.—A small quantity of asbestos was found associated with the talc produced in the state in 1902.

A fire clay was mined near Gay Head, in Dukes county. It generally burns to a white or cream, except the red variety, which burns blue, and upon application of greater heat changes to an iron brown.

Emery was discovered in Chester, Hampden county, in 1864; two years later corundum crystals were also found, and soon thereafter began the first actual mining of emery and corundum in America. In 1902 most of the emery produced in the United States came from this locality. In 1871 the occurrence of corundum in vermiculites with asbestos in olivine rocks, and very similar to the south Appalachian deposit, was discovered at Pelham.[6]

Flint and feldspar were both obtained from a quarry near Huntington, in Hampden county, and the product obtained is ground and screened before being placed on the market. Flint is the principal stone quarried, and in 1902 nearly one-tenth of the total production of the United States was reported from Massachusetts.

A small amount of graphite was mined during 1902, near Sturbridge, in Worcester county. An infusorial earth was mined in Middlesex county.

Iron ore was discovered near Lynn soon after its settlement in 1629, and in 1643 the first iron foundry established in America was located at what is now Saugus Center, in the vicinity of Lynn. This locality furnished most of the iron used in the colony prior to 1671 and the mines were operated at intervals after that time until 1688 when they seem to have been abandoned. The second iron enterprise undertaken in New England was at Braintree, about 10 miles south of Boston. Iron ore was mined there in the early part of 1652,[7] but operations were suspended in the following year on account of the scarcity of ore. Massachusetts was the chief iron center of the continent for a hundred years after its settlement in 1620. During this time bog ore was mined, mostly in the eastern counties. The rich brown hematite ores of western Massachusetts were developed in 1750 and the first furnace was built at Lenox, in Berkshire county, in 1765.[8] This county was the only producer of iron ore in the state during 1902.

The only pyrite mines in Massachusetts are located in Franklin county and were opened in June, 1882. The mineral is an almost pure iron pyrite and the width and continuity of the ore vein, as well as its great length, depth, and purity, make it one of the most remarkable deposits ever known.[9]

Talc is mined in Berkshire county in the vicinity of Dalton. About one-half the product is used by foundries and the balance is prepared as talcum powder or is used as an ingredient of paint.

MICHIGAN.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells in the state of Michigan for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Iron ore.	Copper ore.	Cement.	Coal, bituminous.	Limestones and dolomites.	Gypsum.	All other minerals.[1]
Number of mines, quarries, and wells	203	80	20	11	31	30	6	25
Number of operators	146	41	20	10	30	29	4	12
Salaried officials, clerks, etc.:								
Number	1,585	750	419	102	99	62	127	26
Salaries	$1,840,132	$775,914	$598,076	$131,131	$87,780	$49,264	$171,245	$26,722
Wage-earners:								
Average number	31,951	14,456	13,887	938	1,445	665	359	201
Wages	$20,103,616	$9,132,763	$8,744,892	$535,570	$1,075,805	$325,379	$176,607	$112,600
Contract work	$77,047	$57,382	$11,725		$7,500			$440
Miscellaneous expenses	$3,869,461	$3,004,384	$473,501	$170,477	$106,414	$36,464	$44,715	$33,506
Cost of supplies and materials	$9,341,409	$3,661,194	$4,688,419	$704,237	$82,448	$89,689	$88,634	$26,788
Value of product	$50,157,358	$26,695,860	$18,247,207	$2,134,396	$1,653,192	$657,072	$459,621	$310,010

[1] Includes operators as follows: Clay, 1; graphite, 2; petroleum, 1 (13 wells); sandstones and quartzites, 8 (9 quarries); sandstones and quartzites includes all data for grindstones and pulpstones, and for oilstones, whetstones, and scythestones.

The mineral resources of Michigan are extensive and varied. The iron ore deposits of the Upper Peninsula along the shores of Lake Superior are extensive, and the annual production is enormous. The copper mines of the state are among the richest in the world, and the celebrated Calumet and Hecla mine is claimed to be the most profitable copper mine known. Although coal underlies some 6,700 square miles of the state's area, it is of inferior quality and not pure enough for smelting purposes. The Huron grindstones have been quarried for many years, and Michigan ranks second in their production in the United States, Ohio being first. Valuable deposits of gypsum occur, which, in the vicinity of Grand Rapids and Alabaster, are extensively quarried and used in the manufacture of stucco. The Lake Superior region also produces gold, silver, agate, sardonyx, chalcedony, cornelian, jasper, and opals, as well as roofing slate, freestone, marble, and limestone.[1] Among other minerals to be found are fire clay, marble, ochers, freestones, slates, limestones, and glass sand.[2]

In addition to the minerals mentioned in the foregoing table, the following minerals found in Michigan were not produced in commercial quantities in 1902: Amethysts, barytes, copper pyrites, gold, granite, manganese ores, ocher, serpentine rock, slate, and strontium ore.

The 17 operators who reported active mines and quarries with no production in 1902 were engaged principally in developing copper and iron deposits. These operators employed during the year an average of 353 wage-earners and paid $222,215 in wages; the salaried officials, clerks, etc., received $69,967; the miscellaneous expenses amounted to $103,887, and the cost of supplies and materials to $201,656.

The value of the products of the manufacturing industries of the state, based primarily upon minerals mined or quarried, as reported at the census of 1900, is shown in the following table, which also shows the total value of the products of all manufactures in Michigan for the same year:

TABLE 2.—*Manufactures based primarily on the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$356,944,082
Based upon products of mines or quarries:		
Chemicals and allied products	$7,201,387	
Clay, glass, and stone products	4,325,273	
Iron and steel and their products	34,071,223	
Metals and metal products, other than iron and steel	25,556,939	
Miscellaneous industries	12,576,108	
		83,730,930
All other		273,213,152

From the above table it will be seen that the total value of the products of manufactures in Michigan, based primarily upon minerals mined or quarried, was $83,730,930, or 23.5 per cent of the total. The total value of the output of the mines, quarries, and wells in 1902 was $50,157,358, or 12.3 per cent of the total value of the product of all manufacturing and mining industries.

The average number of wage-earners engaged in the manufacturing industries in 1900 was 162,355, and the total wages paid amounted to $66,467,867. The aver-

[1] King's Handbook of the United States, pages 410 and 411.
[2] Ibid., page 407.

age number engaged in mining in 1902 was 31,951, and their total wages amounted to $20,103,616. The total number of wage-earners, therefore, employed in mining and manufacturing industries was 194,306, and they received in wages $86,571,483. Of this total, manufactures employed 83.6 per cent of the wage-earners and paid 76.8 per cent of the wages. The wage-earners employed in mining industries constituted 16.4 per cent of the total number employed and received 23.2 per cent of the total wages paid.

Table 3, compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals in Michigan from 1890 to 1902, except copper ore, values for which can not be obtained.

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Iron ore.	Cement.	Coal, bituminous.	Limestones and dolomites.	Gypsum.
1890	(1)	(1)	$149,195	$85,952	$192,099
1891	(1)	(1)	133,387	75,000	223,725

[1] Not reported separately. [2] Census figures.

Iron ore.—The existence of iron ore deposits on the southern border of Lake Superior was known to white Indian traders as early as 1830. Their commercial value, however, was not realized until 1844. In 1845 the celebrated Jackson mine in the Marquette district was located and the first forge was built. The first iron was made in this region during the following year.[1] The first iron ore shipped from the Marquette mines for commercial purposes was in 1853, and since that time there has been a steady increase in the output. In 1877 the first shipment of ore was made from the Menominee district and in 1884 from the Gogebic district. The yearly production of the Michigan iron ore mines has increased from 948,553 long tons in 1872 to 11,135,215 tons in 1902. From 1890 to 1900 Michigan ranked first among the iron ore producing states, but since that time it has ranked second, Minnesota being first. By far the greatest quantity of Michigan iron ore is of the red hematite variety, although magnetite is produced to some extent.

The following table, compiled from the reports of the United States Geological Survey, shows the practically steady increase in the iron ore production in this state from 1854 to the present time:

[1] Iron in All Ages, by James M. Swank, page 321.

Copper ore.—The existence of native copper on the southern shore of Lake Superior was first made known by the Jesuit missionaries early in the seventeenth century. Other explorers found copper in that locality in the succeeding century, and in 1770 Capt. Jonathan Carver, of London, published a book, telling of the rich deposits of copper in the Lake Superior region. This led to the formation of a copper mining company in London. During the winter of 1771–72, this company sent over from England a party of miners who conducted operations along the Ontonagon river. The attempt failed, however, and nothing further was done at copper mining for seventy years.[2]

Throughout the entire copper region numerous excavations have been found. It is believed these were made at a very remote period, for the purpose of securing copper. Some of this mine work is on an extensive scale, attaining, in one instance, a depth of 50 feet in the solid rock.[3]

The formation carrying the cupriferous lodes and veins of the Lake Superior district is composed of old lava flows, supplemented by beds of conglomerate which have been formed by the deposition of rocks, broken from adjacent shores, upon old sea beds. This belt of rocks, named after the Keweenaw peninsula, where it predominates, is of considerable extent. It forms a trough or synclinal, the southern edge of which outcrops on the Keweenaw peninsula, and to the westward along the southern shore of the lake.[4]

The discoveries of Dr. Douglas Houghton led to the exploitation of the Lake Superior district, now among the most valuable and productive copper fields in the world. The first copper in any considerable quantity was taken from what was later known as the Cliff mine, in Keweenaw county, in 1846. About 1847 the Minnesota mine, in Ontonagon county, was opened. The mine was closed in 1870, after having paid dividends of

[4] The Copper Handbook, Vol. III, page 106.

$1,820,000 from 17,352 tons 668 pounds of copper produced. The mine has recently been reopened. The famous Calumet and Hecla mine, producing about 8 per cent of the copper output of the world, was opened in 1866. Up to 1903 this mine had contributed about 55 per cent of the total copper production of Michigan.[1]

The now practically abandoned mines on Isle Royal were probably worked long before the arrival of the white man, but the earliest historic explorations were contemporary with those in Keweenaw and Ontonagon counties. Several mines were located and worked to some extent until 1883. At the present time new explorations are being made in this region.[2]

The output of copper from ore mined in Houghton, Keweenaw, and Ontonagon counties was 76,385 long tons in 1902, or 26.8 per cent of the total production for the United States. From 1847 to 1887 Michigan ranked first among the copper producing states, but since that time, with the single exception of 1891, Montana has ranked first and Michigan second. In 1901 Michigan contributed 13.4 per cent of the world's production of copper.

The following table compiled from the reports of the United States Geological Survey, shows the annual production of copper in the United States and in Michigan from 1845 to 1902, and the percentage of Michigan's output to that of the United States:

TABLE 5.—*Annual production of copper in the United States and in Michigan, with per cent of total: 1845 to 1902.*

[1] Census figures.

Cement.—The history of the Portland cement industry in this state begins with the year 1872, when a plant was built near Kalamazoo and operated until abandoned in 1882. No further steps in the development of this industry were taken until 1896 and 1897, when a plant was erected at Union City. This was the beginning of the recent period of rapid and extensive development of the cement industry in Michigan.

The raw materials entering into the composition of the Portland cement thus far made in Michigan are limestone, marl, shale, clay, and gypsum, all of which abound in the state.[3]

Table 6, compiled from the reports of the United States Geological Survey, shows the increase in product of the Portland cement industry in the state from 1896 to 1902.

Coal.—The industry of coal mining in Michigan began in 1835 in Jackson county. This was followed in 1838 by operations on the Grand Ledge, in Ingham and Clinton counties. In 1878 coal was mined in the Owosso district in Shiawassee county, and this field has been worked continuously since that year. Successful operations first began in the Saginaw district and in Bay county in 1895. The large proportion of the product of the smaller mines finds a ready local market, while much of the output from the larger ones goes into Wisconsin, Minnesota, and the Dakotas.[4]

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of coal in the state from 1868 to 1902:

[1] Census figures.

In 1827 an Indian trapper brought a specimen of gypsum which he had picked up on Plaster creek, to the mission located on the present site of Grand Rapids. Little attention, however, was paid to the mining of gypsum until 1838, when Dr. Douglas Houghton, the state geologist, called attention to the deposits. In 1841 the first gypsum mill was built on Plaster creek, in Kent county, and in 1862 the Alabaster quarry and mill in Iosco county were opened.[1] In its ground, uncalcined state gypsum is used as land plaster for fertilizing purposes, but the greater part of the gypsum produced is calcined into plaster of Paris. The total value of gypsum produced in 1901 was $267,243, of which $208,549 was the value of plaster of Paris and $10,708 that of land plaster. In 1902 the total value was $459,621; the value of product calcined into wall plaster and plaster of Paris was $372,821 and that ground into land plaster, $16,340.

All other minerals.—Extensive beds of Potsdam sandstone occur in the northern part of the Upper Peninsula and furnish the best quality of building material found in the state. The stone is of medium fineness of texture and of a light brownish red color, often curiously spotted or mottled with gray, and is known locally as "raindrop stone."[2] The total value of the stone produced by the 9 quarries which operated in 1902 was $188,073, while in 1901 it was $290,578. The principal quarries are located in Baraga, Houghton, Keweenaw, Ottawa, and Marquette counties.

The largest grindstone quarries in the state were opened in 1838 at Grindstone city, Huron county. The Huron grindstone is a very fine grit, soft and wet when fresh, but growing hard and dry upon exposure.[3] In the production of grindstones Michigan is second among the states, Ohio standing first.

The graphite mines are located in Baraga county, the 13 petroleum wells in St. Clair county, and a small quantity of clay is produced in Ontonagon county.

MINNESOTA.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Minnesota for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Iron ore.	Limestones and dolomites.[1]	Sandstones and quartzites.	Siliceous crystalline rocks.	Precious stones.
Number of mines or quarries	176	59	77	13	27	.....
Number of operators	255	31	76	12	26	110
Salaried officials, clerks, etc.:						
Number	675	529	92	18	36	.....
Salaries	$577,336	$430,994	$86,969	$18,654	$40,719	.....
Wage-earners:						
Average number	9,760	8,256	785	305	414	.....
Wages	$6,391,184	$5,376,933	$481,561	$215,068	$317,622	.....
Contract work	$339,244	$338,244	$1,000	.....	.....	.....
Miscellaneous expenses	$4,242,854	$4,134,526	$50,380	$45,740	$12,028	$180
Cost of supplies and materials	$2,868,340	$2,699,115	$103,794	$13,158	$52,273	.....
Value of product	$25,729,545	$23,989,227	$905,857	$347,472	$478,989	$8,000

[1] Includes cement, 2.

By far the most important mineral found in the state is iron ore, Minnesota ranking first in the production of this mineral. The building stones of the state are of excellent quality and of great variety. Natural-rock cement has been manufactured near Mankato for many years, and the famous red pipestone is found in Pipestone county.

In addition to the minerals enumerated in Table 1 the following, which are known to occur in Minnesota, were not produced in commercial quantities during 1902: Feldspar, jasper, molybdenum, reported as occurring in quantities near Portage, Aitkin county, and slate.

In 1902 there were 15 operators, exclusive of those referred to in Table 1, who reported active mines but no production, the work being confined to the care and development of the properties. These operators employed an average of 117 wage-earners and paid $73,700 in wages during the year. The miscellaneous expenses amounted to $2,346 and the cost of supplies and materials to $66,310.

The value of the products of the manufacturing industries of the state, based primarily upon the products of mines and quarries, is shown in the following table, which also shows the total value of products for all manufactures in Minnesota:

TABLE 2.—*Manufactures based primarily upon products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$262,655,881
Based upon products of mines or quarries:		
Chemicals and allied products	$365,101	
Clay, glass, and stone products	3,521,708	
Iron and steel and their products	8,483,578	
Metals and metal products, other than iron and steel	3,210,436	
Miscellaneous industries	12,862,474	
		28,443,297
All other		234,212,584

From the figures in Table 2 it will be seen that the total value of the products of manufactures in 1900, based primarily upon minerals mined or quarried, amounted to $28,443,297, or 10.8 per cent of the total of all manufactures. The total value of the output of the mines and quarries of Minnesota in 1902 was $25,729,545, or 8.9 per cent of the total value of the products of all mining and manufacturing industries in the state.

According to the census of 1900 the average number of wage-earners engaged in the manufacturing industries was 77,234, and the total wages paid amounted to $35,484,825. The average number engaged in mining and quarrying in Minnesota in 1902 was 9,760, and the total wages paid amounted to $6,391,184. The manufacturing and mining industries combined, therefore, gave employment to 86,994 wage-earners and paid $41,876,009 in wages. Of these totals, manufactures employed 88.8 per cent of the wage-earners and paid 84.7 per cent of the wages. Mines and quarries gave employment to 11.2 per cent of the wage-earners and paid 15.3 per cent of the wages.

The following table presents the value of the output of the leading minerals of this state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[1] Not reported. [2] Census figures.

Iron ore.—The Minnesota iron mines thus far developed are in the Mesabi and Vermilion ranges in St. Louis county, and lie about 100 miles north of Duluth. They are about 20 miles apart and extend in an easterly and westerly direction, with the ore deposits scattered along the ranges in groups at irregular intervals; and thus, besides being very narrow, as compared with their length, the ore belts are composed of nonproductive reaches for miles, with occasional groups of rich mines. The ore, confined to red hematite variety, is soft, sometimes yielding 67 per cent of iron, and so low in phosphorus as to come within the Bessemer limit.

The occurrence of iron ore of the azotic system in northern Minnesota was first mentioned in 1850, but no particular importance was ascribed to this ore.[1] H. H. Eames, state geologist of Minnesota in 1865 and 1866, was the first to observe and report iron ore on both the Vermilion and Mesabi ranges and to consider it of any value.[1]

The first iron ore was shipped from the Vermilion range in 1884 and from the Mesabi range in 1892. The total production for 1884 amounted to 62,122 tons. In 1889, with a production of 864,508 tons, the state ranked fifth among the iron ore producing states, while in 1902, with a production of 15,137,650 tons, it ranked first; Michigan second, with 11,135,215 tons; and Alabama third, with 3,574,474 tons. With the exception of Great Britain and the German Empire no country in the world has reached so great a production in any year as Minnesota. Much the greater part of the ore produced goes to furnaces in Pennsylvania, New York, and Ohio, comparatively little being consumed in the state.

The state has adopted the system of leasing its iron lands, and a royalty of 25 cents per ton is imposed on all iron ore mined and shipped from state lands. To the end of the fiscal year ending July 31, 1902, the state had received in royalties on iron ore actually shipped a total sum of $332,119.02.[2]

The following table shows the yearly production of iron ore in Minnesota from 1884 to 1902, inclusive, the figures being taken from the reports of the United States Geological Survey:

TABLE 4.—*Annual production of iron ore: 1884 to 1902.*

[1] Geological and Natural History Survey of Minnesota, Vol. IV., page 583.

[2] Report of State Auditor, 1901–2.

Limestones and dolomites.—The state has extensive deposits of Lower Silurian limestones and dolomites. At present the only ones quarried are located in the counties of Blue Earth, Brown, Dakota, Dodge, Goodhue, Hennepin, Houston, Lesueur, Nicollet, Olmsted, Ramsey, Rice, Washington, and Winona. During 1902, 77 quarries were operated, the value of their product being $905,857, while in 1901 the value of the product from the operating quarries was $522,778. Kasota stone, or pink limestone, which is found in the quarries at Kasota and Mendota, Lesueur county, is much admired and highly valued. Other limestones quarried are usually buff, light blue, or drab in color.

The two cement producing operators, data concerning whose plants are included with limestones and dolomites, manufactured nothing but natural rock cement.

Sandstones and quartzites.—The 13 quarries operating in 1902, in the counties of Carlton, Lac qui Parle, and Pine, produced a product valued at $347,472, while the product of the quarries operated in 1901 amounted to $246,685. The red sandstones of Fond du Lac are the most valuable in the state and closely resemble the Connecticut brownstone, though harder and firmer. These quarries were not operated during the year covered by this report.

Granites.—More than half the state is underlaid by the crystalline class of rocks to which granite belongs. There are large exposures of granite in the northern part of the state which are practically of little value because of their inaccessibility. Those in the southern and western part are of more importance. The first quarry was operated in 1868 in Sherburne county. Minnesota granites are both red and gray in color and vary as to fineness of their grain.[3]

The value of the product from the 27 granite quarries operating in 1902 was $478,989. These quarries were located in Benton, Bigstone, Lac qui Parle, Redwood, Renville, St. Louis, Sherburne, and Stearns counties.

Precious stones.—The value of the catlinite, or red pipestone, quarried in Pipestone county in 1902 was $2,000. This is found nowhere else in the world; is blood red, easily carved, and susceptible of a dull polish. It is famous on account of its earlier use by the Indians for pipes and ornaments.[4]

The value of the output of chlorastrolite, a nonhomogeneous metal found along the shores of Lake Superior, was $4,000; that of agate, found in the sand and gravel around the city of St. Paul, $1,000, and that of mesolite, $1,000.

MISSISSIPPI.

There was no mining on a commercial scale in Mississippi in 1902. The clay deposits, which are widely distributed, have been utilized to some extent for brick.[1] Gypsum, probably the most important deposit of which is located near Cato in Rankin county, has been worked in former years, as have also the gypseous marls, for local use only, of southern Carroll, Attala, Leake, Holmes, northern Madison, Hinds, Rankin, and Scott counties. There was also some development in former years of the hydraulic limestone outcroppings at points in Tishomingo county.[2] Marls and phosphates are found extensively in many counties of the state, and they have been worked to some extent to supply local needs.[1] These phosphates and marls are of great value, and there appears no reason why they should not be developed on a commercial scale.[3]

[1] The New International Encyclopedia, Vol. XII, page 397.
[2] The United States Geological Survey, "Mineral Resources of the United States," 1882, page 698.
[3] Ibid., 1886, page 618.

Sandstones of gray and light buff color occur in Jefferson, Rankin, and Tishomingo counties. This stone, samples of which were exhibited at the New Orleans exposition in 1884–85, is fine grained but rather soft and friable and of doubtful durability as a building stone.[4] Common limestone suitable for local use is found in many sections of the state.[5]

Coal has been found in the vicinity of Alexander, but no production of this mineral has been reported.[6]

Carbonate of iron ores occur over a considerable area in the northern part of the state, and surface conditions indicate that their commercial exploitation is practicable.[7]

MISSOURI.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells in the state of Missouri for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Lead and zinc ore.	Coal, bituminous.	Limestones and dolomites.	Siliceous crystalline rocks.	Clay.	Iron ore.	All other minerals.[1]
Number of mines, quarries, and wells	1,045	374	384	142	11	25	34	75
Number of operators	973	374	345	136	9	25	27	57
Salaried officials, clerks, etc.:								
Number	1,438	777	420	155	16	20	15	35
Salaries	$1,233,811	$727,021	$325,147	$129,291	$11,614	$10,115	$14,766	$15,857
Wage-earners:								
Average number	15,351	6,612	6,501	1,434	179	120	148	357
Wages	$8,757,367	$3,691,923	$3,927,158	$752,178	$104,624	$66,169	$57,475	$157,840
Contract work	$172,514	$105,877	$42,031	$14,595	.....	$77	$500	$9,434
Miscellaneous expenses	$2,118,436	$1,768,458	$250,078	$51,506	$8,256	$11,704	$3,373	$25,061
Cost of supplies and materials	$2,859,018	$2,189,461	$304,821	$262,222	$32,104	$11,123	$26,052	$33,235
Value of product	$20,284,656	$12,555,580	$5,374,642	$1,697,139	$157,708	$134,862	$106,379	$258,346

[1] Includes operators as follows: Barytes, 28 (34 mines); cement, 1; infusorial earth, tripoli, and pumice, 2; mineral pigments, crude, 2; natural gas, 9 (13 wells); nickel and cobalt, 1; petroleum, 2 (10 wells); sandstones and quartzites, 10; sulphur and pyrite, 2.

In the production of zinc Missouri ranks first, the mines in the far southwestern portion of the state yielding a large annual output, and in the central, southeastern, and southwestern parts of the state lead is found in great quantities. Bituminous and cannel coal underlie some 26,000 square miles of the area of the state, being a continuation of the Iowa Coal Measures. The iron fields in the southeastern part of the state produce the red and brown hematite varieties of ore. Quarries of brown, red, and buff sandstone; white, red, and colored marble, hydraulic and Portland cement, rock slate, gypsum and limestone also exist.[1] By virtue of its extensive clay deposits the state ranked seventh in 1902 among the states in the value of its product of clay. Over one-half the output of barytes in the United States is quarried in Missouri.

In addition to the minerals shown in the foregoing table the following minerals are found in this state, but were not produced in commercial quantities in 1902: Gold, gypsum, manganese ore, marble, mica, sandstone, slate, and silver.

In 1902 there were 27 operators who reported active mines but no production, the work being confined to the care and development of the properties. These operators employed an average of 67 wage-earners and paid $43,213 in wages during the year. The salaried officials, clerks, etc., received $10,220, the contract work amounted to $12,149, the miscellaneous expenses to $3,225, and the cost of supplies and materials to $22,352.

[1] King's Handbook of the United States, page 149.

The value of the products of the manufacturing industries of Missouri in 1900, based primarily upon the products of mines and quarries, is shown in the following table, which also shows the total value of all manufactured products in the state, as reported at the Twelfth Census:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$385,492,784
Based upon products of mines or quarries:		
Chemicals and allied products	$6,364,080	
Clay, glass, and stone products	8,533,017	
Iron and steel and their products	27,183,664	
Metals and metal products, other than iron and steel	15,876,274	
Miscellaneous industries	23,002,140	
		80,959,175
All others		304,533,609

From the foregoing table it will be seen that the value of the products of the manufacturing industries, based primarily upon the products of mines and quarries, was $80,959,175, or 21 per cent of the total manufactures reported for 1900. The value of the output of the productive mines, quarries, and wells in Missouri for 1902 was $20,284,656, or 5 per cent of the combined value of the mineral products of 1902 and the manufactured products of 1900.

The Twelfth Census reported the average number of wage-earners engaged in manufactures in Missouri as 134,975 and the wages paid as $60,719,428. The average number engaged in mining in 1902 was 15,351, and the wages paid amounted to $8,757,367. Employ-

ment was therefore given by the two industries to 150,326 wage-earners, who received $69,476,795 in wages. Of these totals, manufactures employed 89.8 per cent of the wage-earners and paid 87.4 per cent of the wages, while mining gave employment to only 10.2 per cent of the wage-earners and paid 12.6 per cent of the wages.

The following table shows the value of the annual production of the principal minerals except lead ore, separate values for which can be obtained only for 1900 and 1901, when the production amounted to $3,726,202 and $4,849,595, respectively:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Zinc ore.[1]	Coal, bituminous.	Limestones and dolomites.	Siliceous crystalline rocks.	Iron ore.	Clay.
1890	$2,256,583	$3,382,858	$1,859,960	$500,642	$561,041	(2)

[1] Values taken from the Fifteenth Annual Report of State Mine Inspector.
[2] Not reported separately.
[3] Includes value of accumulated ores.

Lead and zinc ore.—The principal lead and zinc ore producing districts of Missouri are the southeastern, central, and southwestern. In the southeastern district, including the counties of Jefferson, Madison, St. Francois, and Washington, where lead alone is produced, the ores occur in the older Paleozoic limestones and have very little zinc associated with them. They are disseminated in small grains through the solid limestone, and to distinguish between them and the concentrated ores of the southwest they are called disseminated ores.[1] In the central district but little has been done toward developing lead ore mining. In the southwestern region, commonly known as the Joplin district, which extends into the adjoining corners of Arkansas, Indian Territory, and Kansas, the lead ores occur in connection with zinc, and are found in crevices and cavities in irregular deposits, but at the present time the production of zinc ore in this district is far greater than that of lead.

In 1705 an expedition prepared by the governor of Louisiana ascended as far north as the mouth of the Kansas river in search of precious metals.[2] The celebrated Mine La Motte was discovered in 1715 by M. de la Motte Cadillac.[3] In 1719 the Sieur de Lochon commenced mining on the Meramec river, but with little success.[2] In June, 1721, Sieur Renault, superintendent of the Meramec mines, discovered the mine Renault, which he continued to work until 1742.[2] Work was not again resumed here until the nineteenth century. In 1763 Francis Burton discovered the rich mines now known as the Potosi mines.[2] The first regular shaft was sunk in the Meramec or southeastern district in 1798,[2] and this district has since continued to be a large producer of lead ore.

The lead and zinc ore deposits of southwestern Missouri were discovered in 1851,[4] since which time they have been continuously worked, with the exception of an interruption during the Civil War. In 1872[4] the zinc ore, associated with the lead found in this district, began to attract attention, and has now become more important than the lead ore.

In 1902, only lead ore was produced in Douglas, Franklin, Madison, Miller, Morgan, and St. Francois counties; only zinc ore was produced in Howell, Ozark, and Wright counties; and both ores were produced in Benton, Cole, Greene, Jasper, Jefferson, Lawrence, Moniteau, Newton, and Washington counties.

St. Francois county is the largest producer of lead ore in Missouri; in 1902 its output was 83,401 short tons, valued at $3,584,307, about 67 per cent of the total lead ore production of the state for 1902. Of the 8 operators in this county, 7 had each an output valued in excess of $100,000 and 1 in excess of $1,000,000. Jasper and Newton counties are also very large producers of lead and zinc ores, 39 mines each exceeding $50,000 in value of output.

The following table shows the annual production of lead and zinc ores in Missouri to the present time:

TABLE 4.—*Annual production of lead and zinc ore: 1873 to 1902.*

YEAR.	Zinc ore (short tons).[1]	Lead ore (short tons).[2]	YEAR.	Zinc ore (short tons).[1]	Lead ore (short tons).[2]
1873	960	13,840	1888	61,550	22,610

[2] Figures to 1893 from The Mineral Industry, Vol. II, 1893, page 387.
[3] Not reported separately.
[4] Census figures.

Coal.—The Coal Measures of Missouri, comprising an area of about 22,995 square miles,[5] are part of the Western Interior coal field, which also includes Iowa, Kansas,

[5] Geological Survey of Missouri, 1872, Part II, page 5.

and Nebraska. Some cannel coal is mined, but the bituminous greatly predominates.

It is probable that very little coal was mined in Missouri before 1840,[1] when the earliest reports of production were made. As the state suffers from the disadvantage of being surrounded by other coal producing states whose product can be mined more cheaply, it has to depend very largely upon local markets, and any increased production should therefore be considered as indicating a growth in local population and industry.

Coal production was reported in 1902 from 33 counties, with a total of 384 mines. Macon county produced the greatest quantity, 1,064,726 short tons; Lafayette was next with a production of 543,801 short tons, and Randolph third with 424,167 short tons.

The following table, from the 1902 report of the United States Geological Survey, shows the annual coal production in the state to date:

TABLE 5.—*Annual production of coal, bituminous: 1840 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

Year.	Short tons.	Year.	Short tons.	Year.	Short tons.

1851	125,000	1872	784,000	1893	2,897,442
1852	140,000	1873	784,000	1894	2,245,039
1853	160,000	1874	789,680	1895	2,372,393
1854	175,000	1875	840,000	1896	2,331,542
1855	185,000	1876	1,008,000	1897	2,665,626
1856	200,000	1877	1,008,000	1898	2,688,321
1857	220,000	1878	1,008,000	1899	3,025,814
1858	240,000	1879	1,008,000	1900	3,540,103
1859	260,000	1880	1,680,000	1901	3,802,088
1860	280,000	1881	1,960,000	1902	3,890,154

Limestones and dolomites.—It is probable that underlying 25,000 square miles of this state there are good deposits of limestone,[2] but in 1902, of the 142 quarries in operation, only 47 had a value of product severally in excess of $10,000. The product of the largest quarries located in St. Louis county are light drab in color, and are extensively used in building.

Missouri is sixth in rank among the limestone producing states, the value of the production for 1902 being $1,697,139, an increase over 1901 of $334,867.[3]

Siliceous crystalline rocks.—Although there are almost inexhaustible quantities of granite in the northern part of Iron and Madison counties and the southern portion of St. Francois, only a few quarries are worked systematically.[2] The 11 quarries operated in 1902, all in St. Francois, Wayne, Iron, and Madison counties, produced gray and red granites of various shades. The value of the output in 1902 was $157,708; a gain of $61,902 over 1901.

Clay.—Missouri ranks seventh among the states in the value of the products of clay, which in 1902 amounted to $5,166,414. Of this, $1,832,118, or about 35 per cent, was the value of the common brick produced. The value of the raw clay produced in 1902 was $134,862.[4]

Iron ore.—There are three distinct iron ore fields in Missouri, known as the Iron Mountain, the Southwestern, and the Southeastern districts. Of these the Iron Mountain district is the most important. The first iron ore in Missouri was probably mined about 1816, in which year a small furnace for smelting iron was erected near Stouts creek, in Iron county. In 1845 the Iron Mountain and Pilot Knob region was developed.[5] Over 3,000,000 long tons of ore have been taken from Iron Mountain since its development.

The following table, compiled from the reports of the United States Geological Survey, shows the annual output of the Missouri iron mines since 1884:

TABLE 6.—*Annual production of iron ore: 1884 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Long tons.	YEAR.	Long tons.
1884	233,225	1894	81,926
1885	169,162	1895	12,512
1886	379,776	1896	4,535
1887	427,785	1897	600
1888	217,931	1898	[1] 205,347
1889	265,718	1899	22,720
1890	181,690	1900	41,366
1891	106,949	1901	14,230
1892	118,494	1902	66,308
1893	77,863		

[1] Includes accumulated ores.

All other minerals.—The barytes mined in the state is associated for the most part with limestone, and even where this has become decomposed to some depth, leaving a residual clay-like material, the barytes has not altered. The value of the 31,334 short tons produced in 1902 by the 34 mines was $104,677. The total production for the United States amounted to 61,668 short tons, valued at $203,154.

Portland cement was first produced in Missouri in 1902, but no separate figures for either the production or the value can be shown without exposing individual operations.

The so-called "tripoli," found in Newton county, was mined by two operators in 1902. This material, which is evidently residual silica, is especially adapted for fil-

tering purposes and can readily be cut into any desired shape.[1] The quarries were first opened in 1872.[2]

The mineral pigments, crude, produced in the state in 1902, came from quarries located in Cape Girardeau and Ozark counties.

The 13 gas wells are in Bates, Cass, and Jackson counties. The value of the gas produced in 1902 was $2,154, while in 1889 it was $35,687.

[2] Fifteenth Annual Report Missouri State Lead and Zinc Mine Inspector, 1901, page 164.

The only nickel and cobalt produced in the United States during 1902, except a little from North Carolina and Oregon, were as by-products from Mine La Motte, a celebrated lead mine in Madison county. The 20 tons of matte containing these metals yielded 5,748 pounds of metallic nickel and 3,730 pounds of cobalt oxide.

The 10 productive petroleum wells in 1902 were in Bates and Jackson counties.

The 2 pyrite mines were located in Crawford and Phelps counties.

MONTANA.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Montana for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Copper.	Gold and silver.	Coal, bituminous.	Precious stones.	Limestones and dolomites.	Sandstones and quartzites.	Siliceous crystalline rocks.	All other minerals.[1]
Number of mines or quarries	281	27	176	37	3	10	8	3	17
Number of operators	271	27	176	34	3	10	8	3	10
Salaried officials, clerks, etc.:									
Number	571	310	185	61	2	4	2	1	6
Salaries	$912,477	$494,415	$318,020	$80,674	$1,730	$4,091	$3,900	$1,420	$8,227
Wage-earners:									
Average number	10,539	6,388	2,278	1,587	39	91	57	21	78
Wages	$11,812,150	$7,339,773	$2,688,052	$1,516,043	$43,664	$70,078	$52,117	$26,488	$75,935
Contract work	$64,636	$40,975	$19,161	$1,000					$3,500
Miscellaneous expenses	$893,258	$456,108	$310,145	$118,693	$830	$829	$3,882	$278	$2,493
Cost of supplies and materials	$5,007,102	$3,649,127	$1,069,300	$233,930	$5,920	$8,035	$5,810	$2,583	$32,397
Value of product	$28,265,085	$20,563,353	$4,688,536	$2,443,447	$115,000	$104,725	$85,152	$77,050	$187,822

[1] Includes operators as follows: Corundum and emery, 1; flint, 1; graphite, 1 (8 mines); grindstones and pulpstones (operator reported under sandstones and quartzites); gypsum, 2; iron ore, 3; manganese ore, 1; marble, 1.

Foremost among the minerals in Montana is copper, in the production of which the state leads the world. Millions of dollars worth of gold and silver have been mined since the discovery of gold in the state in 1852. Bituminous coal in large quantities is found along the Missouri and Yellowstone rivers.[1]

Deposits of iron ore, of lead and zinc ores, of graphite and of manganese ore have been found in the state, and have been mined to a greater or less extent. The rocks of the state include granites, sandstones, marbles, and limestones in great abundance and variety. Corundum, flint, quicksilver, tin, platinum, tungsten, and stones suitable for grindstones are also found, and the Montana sapphire is well known among the precious stones.

Of the total value of the product of the mines and quarries in the state in 1902 copper ore contributed 72.8 per cent, more than four times the value of any other mineral produced.

Besides those shown in Table 1, the following minerals occur in the state, but were not commercially produced in 1902: Tin, tungsten, cinnabar, lead and zinc ores, platinum, molybdenum, clay, petroleum, and magnesia.

In addition to the active mines and quarries shown in the foregoing table, 128 operators reported development work in 129 mines and quarries, distributed as follows: Gold and silver, 126; bituminous coal, corundum and emery, and marble, 1 each. The operators employed 77 salaried officials, clerks, etc., who received $83,099, and 520 wage-earners who were paid $592,626 in wages. Contract work amounting to $65,797 gave employment to 810 employees. The total amount expended for miscellaneous expenses was $37,397, and the cost of supplies and materials was $275,796.

The value of the products of the manufacturing industries of the state in 1900, based primarily upon the products of mines and quarries, is shown in the following table, which also shows the total value of products for all manufactures in Montana:

TABLE 2.—*Manufactures based primarily upon the product of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$57,075,824
Based upon products of mines or quarries:		
Clay, glass, and stone products	$498,046	
Iron and steel and their products	1,198,309	
Metals and metal products, other than iron and steel	41,865,685	
Miscellaneous industries	1,929,032	
		45,491,072
All other		11,584,752

The total product of the industries based primarily upon the products of mines and quarries constituted 79.7 per cent of all manufacturing industries of the state in 1900. The value of the product of mines and quarries in 1902 and manufactures in 1900 amounted to $85,340,909; manufactures contributing 66.9 per cent and mines and quarries 33.1 per cent of the combined value. Manufactures in 1900 and mines and quarries in 1902 gave employment to 20,656 wage-earners and paid $19,782,036 in wages, mines and quarries employing 51 per cent of the wage-earners and paying 59.7 per cent of the wages, manufactures giving employment to 49 per cent of the wage-earners and paying 40.3 per cent of the wages.

[1] King's Handbook of the United States, page 516.

Table 3, compiled from the reports of the United States Geological Survey, shows the value of the annual production of gold, silver, coal, limestones and dolomites, and sandstones and quartzites in Montana since 1890. Values for copper ore can not be obtained.

TABLE 3.—*Value of annual production of certain minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Gold.[1]	Silver.[1]	Coal, bituminous.	Limestones and dolomites.	Sandstones and quartzites.
1890	$3,339,000	$20,363,636	$1,252,492	$24,964	$31,648
1891	2,890,000	21,139,394	1,228,630	(2)	35,000
1892	2,891,386	24,615,822	1,330,847	6,000	35,000
1893	3,576,000	21,858,780	1,772,116	4,100	42,300
1894	3,868,429	17,634,220	1,887,390	92,970	16,500
1895	4,101,400	22,715,600	2,850,906	95,121	31,069
1896	4,324,700	21,640,404	2,279,672	83,927	3,250
1897	4,373,400	20,257,487	2,897,408	37,300	25,644
1898	5,126,900	19,144,663	2,324,207	63,196	3,683
1899	4,760,100	20,810,990	2,347,757	113,718	26,160
1900	4,698,000	[3]8,801,148	2,713,707	141,093	59,630
1901	4,744,100	[3]7,879,020	2,009,316	143,866	58,439
1902 [4]	4,373,600	[3]7,019,214	2,443,447	104,725	85,152

[1] Estimates by the Director of the Mint, value of the refined product; silver at coining value. The values given in Table 1 are the values at the mine.
[2] Not reported separately.
[3] Commercial value.
[4] Census figures.

Copper ore.—The city of Butte dates from the discovery in 1864 of placer mines in the Missoula gulch. The placers were in no way remarkable, being duplicated elsewhere in neighboring camps. Following the exhaustion of the auriferous gravels, came the discovery and working of silver bearing ledges in the hills, but these did not add materially to the fame of the district. The Anaconda mine and others of the great properties were bought, developed, and worked with a view to their silver values.[1]

The opening of the Anaconda as a copper mine dates from 1882. At that time the dark red and brown quartz, developed for its gold and silver values, carried only traces of copper, and it was while preparing to mill this ore that the main shaft then being sunk entered the rich copper ledge at a depth of about 300 feet. This led to other discoveries.[1]

In 1870 the Lake Superior region produced 87.2 per cent of the copper product of the country. In 1875 the Lake product constituted 89.4 per cent, and in 1880 it was over 82.2 per cent. In 1882 Montana commenced to produce and advanced steadily and rapidly until in 1887 its copper output exceeded that of the Lake Superior mines. Since that date, with the single exception of 1891, it has held first place not only among the states and territories, but as the largest copper producing district in the world.

The following table shows the annual production of copper in Montana from 1883 to 1902:

[1] Bancroft's History of the Pacific States, page 589 ff.

TABLE 4.—*Annual production of copper: 1883 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Long tons.	YEAR.	Long tons.
1883	11,011	1893	69,290
1884	19,256	1894	81,729
1885	30,267	1895	84,900
1886	25,362	1896	99,071
1887	35,133	1897	102,807
1888	43,704	1898	92,041
1889	43,849	1899	100,503
1890	50,437	1900	120,865
1891	50,028	1901	102,621
1892	72,860	1902	128,975

The output for 1902 was 26,354 long tons in excess of that for 1901, an increase of over 25 per cent; but the 1901 output shows a decrease of 18,244 long tons from the product of 1900, and the 1902 product only exceeds that of 1900, the greatest up to that time, by 8,110 long tons.

Gold and silver.—Although the presence of gold in this section was probably known to the missionaries, they had other motives than the gathering of precious treasures. The discovery of gold is, therefore, apparently due to Francois Finlay, a French half-breed, who had worked in the placers of California, and when returning to the vicinity of his former home, discovered fine float gold on Gold creek, in Deerlodge county, on the western slope of the Rocky mountains. He did little more than prospect the locality.[2]

Subsequently, in May, 1858, James and Granville Stuart, Thomas Adams, and Reese Anderson prospected in Gold creek, finding dirt or gravel that showed as high as 10 cents to the pan. They were forced to abandon the work, however, because of trouble with the Indians and lack of tools and provisions. In the summer of 1860 three small sluice boxes, roughly hewed out of green timber, were operated on Gold creek by Henry Thomas. This was the first actual mining in Montana. Stuart and his party had removed to the vicinity of Fort Bridger, where they lived as traders until 1860, when they returned to investigate the affluents to the valley of the Deerlodge. They prospected during 1861 and found several favorable localities, but it was not until 1862, after receiving from Wallawalla, Wash., 425 miles distant, tools and lumber, that the first string of 10 sluices was set up and worked. They had communicated the news of their discovery to a relative at Pikes Peak, as Colorado was then called, and about the 20th of June, 1862, miners began to arrive at Deerlodge in considerable numbers. The newcomers discovered the placers at Pikes Peak gulch, Pioneer gulch, etc., and from this time the immigration of gold seekers rapidly increased.[3]

[2] Mineral Resources of the United States East of the Rocky Mountains, by James W. Taylor, 1868, pages 39 and 40.
[3] Ibid., pages 39 to 51.

Alder gulch, in Madison county, was discovered in the spring of 1863 by William Fairweather, one of a party of prospectors from Bannock city. The first pan of earth yielded $1.75. Being without provisions, the party hurried back to Bannock city, and returning with friends the gulch was staked off on the 6th and 7th of June, 1863. Within less than two years Alder gulch contained five thriving towns, besides Virginia City, an incorporated city of nearly 10,000 inhabitants. This was the richest and largest "find" ever worked in Montana, and probably in the world, being nearly 20 miles in length and uniformly productive throughout the greater portion. At the head of the gulch the gold was coarse, and many nuggets were picked up varying in value from $200 to $800.[1]

The discovery of Last Chance gulch, near the site of the present city of Helena, in the summer of 1864 was the next of importance. In that summer a party of five or six men are said to have taken from one of the bars in Confederate gulch about 1,400 pounds of gold dust of a value of nearly $300,000.

In addition to the foregoing there were numerous rich diggings found both east and west of the main range. The location and working of vein mines dates from 1864. The Oro Cache lead in the summit district of Alder gulch was discovered early in that year, and work was begun on December 1 of the same year. The Whitlatch Union lead, sometimes called the Owyhee, was discovered in the winter of 1864, and work was begun the succeeding spring.[1]

The following table, compiled from various sources, shows the value of the annual gold and silver production in Montana from 1862 to 1889. The production for the subsequent years has already been given in Table 3.

TABLE 5.—*Value of annual production of gold and silver: 1862 to 1889.*

YEAR.	Gold and silver.[1]	YEAR.	Gold.	Silver.
1862	$600,000	1877	$3,200,000	$750,000
1863	8,000,000	1878	2,260,511	1,669,635
1864	16,000,000	1879	2,500,000	2,225,000
1865	18,000,000	1880	1,805,767	2,905,068
1866	17,500,000	1881	2,330,000	2,630,000
1867	12,000,000	1882	2,550,000	4,370,000
1868	15,000,000	1883	1,800,000	6,000,000
1869	9,000,000	1884	2,170,000	7,000,000
1870	9,100,000	1885	3,300,000	10,060,000
1871	8,050,000	1886	4,425,000	12,400,000
1872	6,068,339	1887	5,230,000	15,500,000
1873	5,178,047	1888	4,200,000	17,000,000
1874	3,844,722	1889	3,500,000	19,393,939
1875	3,573,600			
1876	[2]			

[1] From 1862 to 1867, inclusive, compiled from "Mineral Resources of the United States East of the Rocky Mountains," by James W. Taylor, 1868, page 52; 1868 to 1879, inclusive, from "The Mineral Industry," 1892, page 188; and 1880 to 1889, inclusive, from United States Geological Survey, "Mineral Resources of the United States," 1892, page 75.

[2] Not reported.

Coal, bituminous.—The occurrence of good steam coal accessible to the Northern Pacific system was a question of importance in the development of the mining and manufacturing interests of the Northwest. A vast amount of lignite was known and in places worked, but was so poor in quality that coal was brought from Pittsburg to mix with it. In 1881 true bituminous was known to occur in but two places in Montana, one near Bozeman canyon and the other on the summit of Mullens Pass. In that year, taking these occurrences as clews, the Bozeman outcroppings were traced several miles. Another outcrop was found for 24 miles, south of Wilkeson through the forests of the Cascade mountains, and several other less important bituminous fields were discovered. The bituminous coal field north of the forty-fifth parallel is on the west flank of the Cascade and the east flank of the Rocky mountains, the few occurrences between these ranges being insignificant.

The great plains for miles away from the mountains are underlaid with beds of lignite of inferior quality, often attaining a thickness of 7 or 8 feet. As the mountains are approached the lignite, as a rule, disappears, giving place to true bituminous, and frequently a good coking coal, though the seams are of less thickness than the lignite.[2]

The production of coal in the Bozeman field began in January, 1883, and operators in the Gardiner field, along the Yellowstone, in Gallatin county, reported their first production the same year.[3]

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of coal in Montana from 1883 to 1902:

TABLE 6.—*Annual production of coal, bituminous: 1883 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.
1883	19,795	1893	892,309
1884	80,376	1894	927,395
1885	86,440	1895	1,504,193
1886	49,843	1896	1,543,445
1887	10,202	1897	1,647,882
1888	41,467	1898	1,479,803
1889	363,301	1899	1,496,451
1890	517,477	1900	1,661,775
1891	541,861	1901	1,396,081
1892	564,648	1902	1,560,823

The total value of the coal product of the state in 1902 was $2,443,447, the largest value being shown for Cascade county, followed by Carbon, Park, Gallatin, Choteau, and Fergus, in the order named. Production is also reported for Deerlodge and Meagher counties, their combined product being valued at $2,012.

Precious stones.—The only systematic mining that has been undertaken for sapphires is in Montana. Sapphires were first found in this state by miners who were washing the gravels of the bars on the Missouri river for gold. These were first described in 1873, but actual mining did not begin until 1891. These bars are located from 12 to 18 miles northeast of Helena and

[1] Mineral Resources of the United States East of the Rocky Mountains, 1868, pages 39 to 51.

[2] Tenth Census, Vol. XV, pages 691 and 692.

[3] United States Geological Survey, "Mineral Resources of the United States," 1883, page 53.

have been followed from Canyon Ferry to American bar, a distance of about 12 miles. Sapphires are also found in the gravel of Maple gulch, about 1 mile above Emerald bar, the intermediate gravels being barren. These stones are for the most part of a pale green or greenish yellow color, with an occasional pink and yellow, while those approaching a red or blue color are extremely rare. Sapphire has also been found at Rock creek, Cottonwood creek, and Yogo gulch. From these deposits stones of deeper color have been obtained, those from Rock and Cottonwood creeks ranging from red to blue, and those from Yogo gulch being all blue.[1] Smoky quartz has also been found at Three Mile gulch, near Helena. A gigantic crystal weighing 93½ pounds was found on Clear creek, in Jefferson county. Montana is the chief western source of supply for the amethyst. In 1895 a crystal weighing 12 pounds was found on Granite creek, and in 1900 remarkable discoveries were made in Jefferson county about 22 miles southeast of Butte. The amethyst in this locality occurs in fine crystals curiously mingled with quartz. The amethyst itself is free from foreign substances, though occasionally parts of the same crystals are composed of tourmaline.

Besides those already named, beryl, aquamarine, garnet, chrysoberyl, white topaz, opal, agate, and moss agate are frequently found in the gold bearing gulch soils.[2]

Limestones and dolomites.—Though the occurrence of limestone is known in almost every one of the 26 counties and the Crow reservation, only 8 reported the quarrying of limestone in 1902. The largest product was shown for Cascade county and the second largest for Jefferson county, their entire production being used as blast furnace flux. Lewis and Clarke county was third, where about one-fourth of the production was used for building, more than one-half for blast furnace flux, and the remainder for flagging. Powell county was fourth, the entire production being burned into lime. The fifth county in value of product is Flathead, followed by Park, Sweet Grass, and Yellowstone in the order named. Of the total production in the state, $88,000 was used for flux; $8,775 for lime burned; $6,375 for building purposes; and the remainder for flagging and rubble.

Sandstones and quartzites.—A fine light gray sandstone, somewhat resembling the Berea, Ohio, stone, occurs in considerable abundance in Rocky canyon, Gallatin county, the formation permitting the removal of large blocks which work readily when first removed, but harden on exposure. A compact, red quartzite, found near Salesville, in the same county, and a fine, very light stone quarried near Dillon, in Beaverhead county, are coming into use.[3] Sandstone also forms one of the strata of the Coal Measures of Montana, often cleaving the coal seam and sometimes attaining a thickness of 50 feet.[4]

In 1902 Yellowstone county showed the largest production, $62,162. The amount used for building purposes was $54,430, of which $51,638 was the value of dressed stone. The other counties reporting were Cascade and Flathead.

Siliceous crystalline rocks.—A fine grained light gray granite occurs in Lewis and Clarke county, and a coarse hornblende-mica granite is found in the copper region near Butte. This latter rock is of good quality, but requires careful selection, as those portions in close proximity to the ore veins are charged with pyrite, which oxidizes on exposure. There is abundance of granite in the state, but for lack of a market quarrying is not extensive.[5] Two of the three quarries reporting in 1902 were located in Lewis and Clarke county, and the third in Jefferson county, the total output being valued at $77,050. Almost the entire production from Lewis and Clarke county was dressed for building purposes. Of the total production the value of stone for building purposes amounted to $32,600, and that used for riprap to $43,800.

All other minerals.—The property of the Montana Corundum Company, consisting of four claims and the mineral rights in 3,000 acres of land, was located in 1901. The ground upon which the corundum was discovered has been used as a stock range for nearly thirty years, and no doubt in the last ten years hundreds of people have passed over the "float" crystals without stopping to inquire their nature. A farmer and prospector exhibited, in the winter of 1900–1901, to a druggist from Hoopston, Ill., a crystal and a pocketknife, the blade of which gave evidence of the hardness of the crystal found. The druggist recognized the mineral, and after a careful search of the vicinity where the crystal was found definitely located the vein. A shaft 85 feet deep was sunk, from the bottom of which a drift was run along the vein—to the west 165 feet and to the east 72 feet. The vein thus far developed measures from 26 to 48 inches between the walls, with a pay streak varying from 14 to 42 inches in width. Numerous shafts, surface crosscuts, and pits have prospected the vein for a distance of over 1½ miles.[6]

In 1902 one flint quarry was reported as in operation near Basin, in Jefferson county, the entire production being sold crude as a flux in metallurgical operations.

[1] Bureau of Agriculture, Eighth Biennial Report, 1902, "Labor and Industry of Montana," pages 312 to 320.

[5] Stones for Building and Decoration, page 75.

[6] Bureau of Agriculture, Eighth Biennial Report, "Labor and Industry of Montana," page 443.

Prior to 1887 a deposit of graphite was discovered in Van Camps canyon, 18 miles from Dillon, but it was not systematically developed until 1901. The vein is a true fissure, and varies in width from 12 inches to a few feet. The ore has been tested and declared equal to the best grades imported from Ceylon.[1]

The sandstone quarries at Columbus, Yellowstone county, reported a portion of their product as manufactured into grindstones. It is a fine even-grained sandstone, and produces an article equal to the well-known Berea grindstone.[2]

Gypsum was discovered in 1893, in Carbon county, 8 miles from Bridger, the nearest railroad station, which is 29 miles from Billings on the main line of the Northern Pacific. Active development began in 1894, and in spite of the long haul by wagon the gypsum has been placed in successful competition with the eastern product. The deposit, from 2 to 10 feet thick, lies almost flat, about 30 feet below the surface of the ground. In 1900 another quarry was opened in Cascade county; the gypsum vein is about 16 feet thick and lies flat under several feet of limestone. The mill of this plant is located on a branch of the Montana Central Railway; the mine being directly back and up the hill, gravity is largely helpful in handling the rock.[3]

The work of the Northern Transcontinental Survey proved the existence of extensive deposits of iron ore in the mountain region of Montana. Notable among these is a mass of magnetic ore on East Boulder creek, Gallatin county, and on Cable mountain in Deerlodge county. The ore from the latter locality will average from 55 to 60 per cent metallic iron, is low in phosphorus and sulphur and practically free from titanium.[4]

In previous years the state has been comparatively unimportant as far as the production of manganese ore is concerned. In 1902, 9,000 tons of ore were mined, and stocked at the mines, from two deposits in Jefferson county. Analysis of the ore is said to show 45 per cent and over of manganese. It would also be valuable as a flux.[5]

About 5 miles southwest of the city of Helena a vast ledge of marble containing several grades of this mineral has been located.

NEBRASKA.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Nebraska for 1902.

TABLE 1.—*Summary: 1902.*

	All minerals.[1]
Number of mines or quarries	36
Number of operators	35
Salaried officials, clerks, etc.:	
Number	12
Salaries	$8,001
Wage-earners:	
Average number	178
Wages	$95,935
Miscellaneous expenses	$2,790
Cost of supplies and materials	$11,173
Value of product	$148,391

[1] Includes operators as follows: Infusorial earth, tripoli, and pumice, 1 (2 quarries); limestones and dolomites, 33; sandstones and quartzites, 1.

Of chief importance among the natural resources of Nebraska are its rocks of various kinds and qualities. Sandstone, chalk rock, limestone, and magnesia rock abound. Fire and mineral clays are of extensive occurrence in the northern counties, and a fuller's earth of superior quality was discovered in Cherry county a few years ago.[1] Bituminous and lignite coal underlie the eastern counties and the valley of the Republican river.

These beds furnish fuel for local use, but up to the present time the deposits have not been worked commercially.[2]

Table 2 shows the value of the products of the manufacturing industries of Nebraska, based primarily upon minerals mined and quarried, as well as the value of all manufactured products of the state, as reported at the census of 1900.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$143,990,102
Based upon products of mines or quarries:		
Chemicals and allied products	$954,849	
Clay, glass, and stone products	1,365,120	
Iron and steel and their products	1,012,236	
Metals and metal products, other than iron and steel	24,671,289	
Miscellaneous industries	4,097,761	
		32,101,255
All other		111,888,847

From the foregoing table it will be seen that the value of the products of manufactures, based primarily upon minerals mined and quarried, was $32,101,246, or 22.3 per cent of the total. The value of the output of the mines and quarries of Nebraska in 1902 was $148,391, or about one-tenth of 1 per cent of the value of all its manufactured products in 1900.

The average number of wage-earners engaged in manufactures in Nebraska in 1900, as reported at the Twelfth Census, was 24,461, and the wages paid them amounted to $11,570,688. The average number of wage-earners engaged in mining and quarrying in 1902 was 178, and the wages paid them amounted to $95,935. The combined figures give 24,639, as the number of wage-earners, and $11,666,623 as the wages paid in the combined industries. Manufactures employed 99.3 per cent of the wage-earners, and paid 99.2 per cent of the wages; while mines and quarries employed only seven-tenths of 1 per cent of the wage-earners and paid eight-tenths of 1 per cent of the wages.

Limestones and dolomites.—The carboniferous limestone of this state is suitable for building, as is also the siliceous limestone found in Sarpy county.[3]

The 33 quarries operating in 1902, all of them in Cass, Cheyenne, Furnas, Gage, Greeley, Johnson, Nemaha, Sarpy, and Thayer counties, had an output valued at $145,473. Of this amount $69,330 was reported from Cass county, $34,237 from Gage, and $22,795 from Nemaha.

The following table, compiled from the reports of the United States Geological Survey, shows the annual value of limestone quarried in Nebraska from 1890 to 1902:

TABLE 3.—*Value of annual production of limestones and dolomites: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Value.	YEAR.	Value.
1890	$207,019	1897	$42,359
1891	175,000	1898	78,493
1892	180,000	1899	125,017
1893	158,927	1900	107,305
1894	8,228	1901	154,717
1895	7,376	1902[1]	145,473
1896	10,655		

[1] Census figures.

The production of the two pumice quarries and of the single sandstone quarry can not be shown without disclosing individual operations.

NEVADA.

Table 1 is a summary of the statistics for the productive mines and quarries in Nevada for 1902.

TABLE 1.—*Summary: 1902.*

	Total.	Gold and silver.	Sandstones and quartzites.	All other minerals.[1]
Number of mines or quarries	114	104	3	7
Number of operators	121	104	3	14
Salaried officials, clerks, etc.:				
Number	146	136	.....	10
Salaries	$222,098	$210,838	.....	$11,260
Wage-earners:				
Average number	1,132	1,075	2	55
Wages	$1,205,565	$1,162,337	$1,583	$41,645
Contract work	$7,944	$7,944	.....	.....
Miscellaneous expenses	$177,355	$172,206	$351	$4,798
Cost of supplies and materials	$623,457	$599,928	$250	$23,279
Value of product	$3,518,430	$3,409,348	$6,115	$102,967

[1] Includes operators as follows: Borax, 1; copper ore, 1; gypsum, 1; limestones and dolomites, 1; precious stones, 8 (1 mine); siliceous crystalline rocks, 1; sulphur and pyrite, 1.

The discovery and development of mineral deposits, especially that of the Comstock lode, is responsible for the settlement and indeed the very existence of Nevada, and the history of mining is therefore to a great extent the history of the state.[1] Until the news of precious metal discoveries and the consequent influx of prospectors, Nevada was largely a desert wilderness, invaded only by missionaries and a few dauntless exploring parties. The early history is to a certain extent identified with that of Utah, Arizona, portions of Colorado, Wyoming, Oregon, and northern California,[2] and it was not until March 2, 1861, that the confines were fully established and Nevada took position as a recognized territory, advancing to statehood October 31, 1864.

Certain minerals occur in considerable quantities in various portions of the state, for which no commercial production was shown for 1902. Among the most important of these are barytes (heavy spar), found in Humboldt county; coal in the form of lignite, in Esmeralda county; cinnabar, the ore containing quicksilver, near Steamboat, in Washoe county; graphite or plumbago and magnetic iron ore (magnetite), in Humboldt county; iron ore (hematite), in Elko and Churchill counties; iron sulphuret (pyrite), in Lander and many other counties; cerussite (lead carbonate) and galenite, in Eureka county; pyrolusite or manganese dioxide, at Dun Glen and near Golconda, in Humboldt county; and roofing slate, in Esmeralda county.

In addition to the productive mines and quarries in Table 1, development work, confined to gold and silver, was reported by 82 operators. During 1902 these operators employed 574 wage-earners and paid $656,169 in wages. The 142 salaried officials, clerks, etc., received $181;172; the contract work amounted to $27,133; the miscellaneous expenses to $70,435; and the cost of supplies and materials to $454,077.

The manufacturing industries of a state depend somewhat upon the character of its mineral deposits, some of the most important manufactured products being based primarily upon materials obtained in mines and quarries. The following table will illustrate the extent to which this is true of Nevada:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.		Value of product.
All manufactures		$1,643,675
Based upon products of mines or quarries:		
Chemicals and allied products	$20,950	
Clay, glass, and stone products	52,350	
Metals and metal products, other than iron and steel	108,184	
Miscellaneous	139,876	
		321,360
All other		1,322,315

As shown in Table 2, the manufactured products based upon the product of mines and quarries form about one-fifth of the entire product of manufactures reported in 1900. During the same year there were employed in all branches of manufactures in the state 601 wage-earners, who were paid $416,732 in wages. In 1902 there were employed in the mines and quarries of the state 1,132 wage-earners, who received $1,205,565 in wages. Comparing these two branches of industry, it is disclosed that 34.7 per cent of the wage-earners of the combined industries, receiving 25.7 per cent of the wages, were employed in manufacturing, while 65.3 per cent of the wage-earners, receiving 74.3 per cent of the wages, were employed in mining.

Gold and silver.—In 1902 Nye county was first in precious metal production, the Tonapah mining district taking rank as the principal mining center of the state. Storey county is second in importance with its famous

[1] History of Nevada, by Hubert H. Bancroft, page 92.
[2] Ibid., page 66.

Comstock lode, while Lincoln county, which stood first in gold and silver production in 1901, has now dropped to third place. Eureka and Elko counties are respectively fourth and fifth in rank and both show an increased production, still retaining their former relative positions among the gold and silver counties of the state. In the order of their reported production may also be mentioned Lyon, White Pine, Lander, Washoe, Humboldt, Esmeralda, Ormsby, Churchill, and Douglas counties.[1]

The following table, compiled from the reports of the Director of the United States Mint, shows the annual production of gold and silver from 1890 to 1902:

TABLE 3.—*Annual production of gold and silver: 1890 to 1902.*

[Reports of the Director of the Mint.]

YEAR.	GOLD.[1]		SILVER.[1]	
	Quantity (fine ounces).	Value.	Quantity (fine ounces).	Coining value.
1890	135,450	$2,800,000	4,450,000	$5,753,535
1891	99,169	2,050,000	3,520,000	4,551,111
1892	76,021	1,571,500	2,244,000	2,901,333
1893	46,367	958,500	1,561,300	2,018,651
1894	55,042	1,137,819	1,035,151	1,338,377
1895	75,088	1,552,200	956,200	1,236,290
1896	119,404	2,468,300	1,048,700	1,355,895
1897	143,983	2,976,400	1,228,900	1,588,881
1898	144,859	2,994,500	805,000	1,040,808
1899	107,344	2,219,000	843,400	1,090,457
1900	97,050	2,006,200	1,358,700	[2]842,394
1901	143,374	2,963,800	1,812,500	[2]1,087,500
1902	140,059	2,895,300	3,746,200	[2]1,985,486

[1] Estimates of the Director of the Mint for refined product. The values given in Table 1 are the values at the mine.
[2] Commercial value.

As seen from Table 3, the production of gold during 1898 was greater than that of any other year shown, and the product during 1897, 1898, and 1901 was slightly more than that reported for 1902. Both the quantity and value of silver produced in 1902 were greater than for any other year since 1890, in which year and in earlier years a larger production is reported. The smallest production of gold was reported in 1893 and of silver in 1898.

Gold was discovered in Nevada in Gold canyon, near Dayton, by Abner Blackburn, in July, 1849.[2] In the same year an immigrant named Hardin discovered silver in the Black Rock range, in Humboldt county.[3] Other placer and quartz mines were located in various parts of what is now Nevada, but Gold Canyon was the only district worked prior to 1857. The Comstock lode of gold and silver ore was discovered June 11, 1859, and from this time on the mining interests of Nevada have been a matter of brilliant history.[4]

The gold hunters, working up the ravines from Gold canyon and Six Mile canyon, in 1859 came across what is known as the "Comstock lode," so named for Henry Comstock, one of the claim locators. This famous channel of silver and gold ore is about 3 or 4 miles long and a quarter of a mile wide, and extends nearly north and south along the eastern slope of Mt. Davidson, principally in Storey county, at a distance of about 20 miles from the California boundary. At first the ore in the Comstock lode was worked for gold alone, but later the black metallic substance occurring so persistently in connection with the gold was discovered to be a rich sulphuret of silver.[5]

From that time on until 1877 this locality was increasingly productive. During the bonanza years—1873 to 1877—the value of the ore produced each month ranged from about $2,000,000 to $3,000,000.

The following table, compiled from the reports of the Director of the Mint, shows the quantity and value of the annual production of gold and silver from the Comstock lode district from 1859 to 1902:

TABLE 4.—*Annual production of gold and silver in the Comstock lode district: 1859 to 1902.*

[Reports of the Director of the Mint.]

YEAR.	TOTAL.		Silver.	Gold.
	Quantity (tons of ore).	Value.		
1859		$30,000.00		$30,000.00
1860	10,000	750,000.00	$200,000.00	550,000.00
1861	140,000	3,500,000.00	1,000,000.00	2,500,000.00
1862	250,000	7,000,000.00	2,350,000.00	4,650,000.00
1863	450,000	12,400,000.00	7,460,000.00	4,940,000.00
1864	680,450	16,000,000.00	9,600,000.00	6,400,000.00

1871	409,718	10,249,528.65	6,149,717.19	4,099,811.46
1872	384,668	12,236,399.65	7,341,839.79	4,894,559.86
1873	448,301	21,671,980.53	13,003,187.13	8,668,793.40
1874	526,742	22,476,785.15	13,486,071.09	8,990,714.06
1875	546,425	25,825,521.54	15,495,312.92	10,330,208.62
1876	598,818	31,618,660.20	18,971,196.12	12,647,464.08
1877	562,519	36,301,536.70	21,780,922.02	14,520,614.68
1878	272,909	19,661,394.11	11,796,836.47	7,864,557.64
1879	178,276	7,003,485.82	4,202,091.49	2,801,394.33
1880	172,399	5,129,015.00	3,077,409.00	2,051,606.00
1881	76,049	1,075,620.00	645,372.00	430,248.00
1882	90,181	1,743,464.00	1,046,078.40	697,385.60
1883	125,914	2,006,348.83	1,203,809.29	802,539.54
1884	188,369	2,838,752.00	1,577,438.40	1,261,313.60
1885	226,147	3,144,602.29	1,415,071.04	1,729,531.25
1886	238,780	3,736,218.46	1,681,298.31	2,054,920.15
1887	223,682	4,511,230.63	2,030,053.78	2,481,176.85
1888	271,152	7,627,267.73	4,458,058.66	3,169,209.07
1889	286,144	5,949,923.27	3,358,949.95	2,590,973.32
1890	286,075	4,980,872.59	2,988,523.56	1,992,349.03
1891	188,647	3,452,142.55	2,071,285.53	1,380,857.02
1892	133,678	2,173,247.63	1,130,088.77	1,043,158.86
1893	109,780	1,872,104.24	748,841.70	1,123,262.54
1894	97,049	1,281,467.72	512,587.09	768,880.63
1895	63,558	914,789.47	365,915.79	548,873.68
1896	39,240	567,088.93	226,835.57	340,253.36
1897	17,850	373,014.39	149,205.76	223,808.63
1898	10,766	205,039.81	82,016.92	123,023.89
1899	6,780	171,677.90	68,671.16	103,006.74
1900	35,300	700,865.26	319,441.70	381,423.56
1901	56,577	1,267,509.00	521,032.00	746,477.00
1902	96,490	1,280,975.55	495,944.96	785,030.59
Total	10,851,748	352,798,425.00	204,653,039.80	148,145,385.20
Total mill tailings		18,449,863.16		
Grand total		371,248,288.16		

From 1877 to 1900 a decreasing production indicated that the rich ore body was probably becoming exhausted. The increased production shown for 1901 and 1902 is largely due to the introduction of improved electrical machinery.

[1] Annual Report of the Director of the Mint, 1902, page 152.
[2] Harper's Encyclopedia, Vol. IX, page 434.
[3] History of Nevada, page 103.
[4] Ibid., pages 94 and 95.
[5] Report of the Director of the Mint, 1900, page 155

The Sutro tunnel, projected by Adolph Sutro in 1869 and finished in 1879, is nearly 4 miles long, extending from the low hills bordering Carson river valley westward to the Comstock lode. The chief objects of the tunnel were to improve the drainage and ventilation and facilitate the working of the Comstock lode, and for this service all the mining companies pay a royalty. This tunnel has been principally valuable in drainage, and without it certain of the deep workings of the lode could not have been operated successfully on account of the flooding of the lower levels of the mines.

Quartz and porphyry are generally the accompanying vein matter met with in the Comstock lode, the gangue carrying the precious metals being quartz and the inclosing walls a diorite or syenite on the west and on the east a porphyrite or trachyte formation, seamed with quartz and clay. The ore obtained, both gold and silver, is free milling and is not refractory with foreign mineral complications.[1]

The rich deposit of precious metals in the Tonapah mining district in the north central portion of Nye county, near Mt. Oddie, was discovered in April, 1900, by James L. Butler, and in August of the same year he located the eight claims now forming the regular Tonapah group. A plan of leasing the ground in small sections on a 25 per cent royalty was adopted by Mr. Butler and a considerable quantity of ore was extracted on this basis.[2]

The following table, compiled from the reports of the Director of the Mint, shows the quantity of the production of ore, and the value of its precious metal contents, in the Tonapah district for 1901 and 1902:

TABLE 5.—*Annual production of gold and silver in the Tonapah district: 1901 and 1902.*

[Reports of the Director of the Mint.]

YEAR.	TOTAL.		Silver.[1]	Gold.
	Quantity (tons of ore).	Value.		
1901	2,534	$576,146	$374,110	$202,036
1902	11,258	1,793,129	1,234,271	558,858

[1] Commercial value.

Prior to January, 1902, the work done was altogether individual, but in that year a systematic development of the property was begun by a Philadelphia syndicate which had purchased the Tonapah mines. Several shafts have been started and the deep workings show an improvement both in the quantity and quality of ore.[3]

The mining industry was considerably hampered by inadequate transportation facilities during these years. Food, supplies, and even drinking water had to be carted to the camp from other localities and the ore transported 60 miles to the nearest railroad.[4] A railroad is now being built to the mines.

The Mizpah ledge has received the greatest amount of attention, although the surface indications point to rich deposits awaiting development in other of the fifteen ledges thus far discovered in this group. The chutes in which the ore is found are sometimes from 6 to 8 feet and even more in thickness, and pitch to an angle of about 35°. The gangue substance is quartz and the ore a fine grained black sulphuret, containing much chloride of silver and small amounts of iron and manganese. There is no free gold.[4]

Sandstones and quartzites.—The commercial production of sandstone in 1902, reported only in Nye county, amounted to $6,115, of which $2,383 was sold in the rough for building purposes and $3,657 for rubble.

All other minerals.—A considerable quantity of sulphur was produced in Humboldt county during 1902. Operations were reported by one company only and the statistics are therefore not shown separately.

The only precious stone reported as produced in the state in commercial quantities during 1902 was turquoise, found principally in Lincoln county. Only one company is regularly engaged in mining gems, but numerous miscellaneous findings are reported to the small dealers.

The state's production of gypsum in 1902 was all mined in Lyon county and is reported by one company.

Borax deposits occur in Esmeralda and Churchill counties, only the former reporting a production in 1902. The borax obtained in Esmeralda county was treated by boiling, evaporation, and crystallization before being placed on the market.

Deposits of limestone predominate in the mountains of Nevada and are marked by overflows of basaltic trap rock and trachytic lavas.[5] The production during 1902 was reported from Lyon county, near Dayton.

Granite was quarried in Washoe county during 1902, and the production was sold for building and monumental purposes and for curbing.

Copper occurs in fissure veins with gold, silver, and lead, chiefly in the form of sulphide, carbonate, or oxide. A small amount was produced in 1902, all of which was subjected to the smelting process before being marketed.

NEW HAMPSHIRE.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of New Hampshire for 1902.

TABLE 1.—*Summary: 1902.*

	Total.	Siliceous crystalline rocks.	All other minerals.[1]
Number of mines or quarries	56	51	5
Number of operators	62	49	13
Salaried officials, clerks, etc.:			
Number	92	87	5
Salaries	$68,971	$65,648	$3,323
Wage-earners:			
Average number	1,253	1,219	34
Wages	$806,494	$791,196	$15,298
Miscellaneous expenses	$26,993	$26,719	$274
Cost of supplies and materials	$134,128	$132,122	$2,006
Value of product	$1,176,312	$1,147,097	$29,215

[1] Includes operators as follows: Infusorial earth, tripoli, and pumice, 1; mica, 2; oilstones, whetstones, and scythestones (2 mines, operator reported in Arkansas); precious stones, 10 (no mines).

The value of the mineral production for the state in 1902, $1,176,312, is only two-tenths of 1 per cent of the total value of all minerals mined or quarried in the United States during the year. Of the 50 states and territories from which mining operations were reported, New Hampshire ranked 41. The state produced in commercial quantities only five classes of minerals. These were, in the order of their importance, siliceous crystalline rocks, including granite, trap rock, and similar stones; mica; infusorial earth, tripoli, and pumice; oilstones, whetstones, and scythestones; and precious stones.

The value of the output of siliceous crystalline rocks for the state during 1902 was $1,147,097. This production consisted of building stone, rough and dressed, valued at $619,916; of stone for monumental purposes, valued at $346,735; of stone converted into paving blocks, valued at $101,548; and of stone for a variety of other purposes, valued at $78,898.[1]

In addition to the minerals named above, others occur in greater or less abundance, but were not mined in commercial quantities. The more important are clay, monazite, copper ore, and talc and soapstone.[2] Monazite has been identified with the granites in many localities, but nowhere in sufficient quantities or purity to warrant its exploitation.[3] Talc has been mined in small quantities in connection with other minerals.[4]

[3] Ibid., 1901, page 950.
[4] Ibid., 1900, page 777.

The following table shows the value of the products of manufactures in 1900, based upon the products of mines and quarries, compared with the value of products of all manufactures:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$118,709,308
Based upon products of mines or quarries:		
Clay, glass, and stone products	$2,080,657	
Iron and steel and their products	4,164,207	
Metals and metal products, other than iron and steel	956,330	
Miscellaneous[1]	3,422,200	
		10,623,394
All other		108,085,914

[1] Includes the products of 1 producer of chemicals and allied products in order to avoid disclosing its operations.

This table shows that the value of all manufactures for New Hampshire in 1900 was $118,709,308, and that the value of manufactured products based primarily on the products of mines and quarries was $10,623,394, or 8.9 per cent of the total. Tables 1 and 2 also show that the combined value of manufactures for 1900 and of mineral products for 1902 was $119,885,620. Of this amount, manufactures contributed 99 per cent and mines and quarries 1 per cent.

During 1902 there were employed in mines and quarries 1,253 wage-earners, who received $806,494 in wages. The census of 1900 reported 70,419 wage-earners employed in manufactures, at wages amounting to $27,620,247. On the basis of these figures, wage-earners engaged in manufactures constituted 98.3 per cent of the total number, and their wages amounted to 97.2 per cent of the total wages. It follows, therefore, that the wage-earners employed in mining industries constituted only 1.7 per cent of the total number employed and that they received 2.8 per cent of the wages.

Siliceous crystalline rocks.—Granite is found in every section of the state in quantities practically inexhaustible.[5] New Hampshire is one of the most mountainous of the New England states. The White mountains, extending through the upper half of the state, are practically solid granite. As early as 1623 stone was used for building construction;[6] and judging from the fact that the first settlement was made in the vicinity of prominent granite deposits, it is reasonable to suppose

[5] Report of New Hampshire Bureau of Labor, Vol. VI, 1901–2, page 16.
[6] History of New Hampshire, by J. N. McClintock, page 29.

that this stone was used. The old state prison, erected at Concord in 1812, and the statehouse, built in the same city in 1816–19, were built of this granite, quarried in the immediate vicinity.[1] The admirable state of preservation of these buildings is evidence of the excellent quality of the stone. The New Hampshire granite is known to commerce as the muscovite-biotite granite, and is considered one of the most valuable in the United States. In texture it is as fine as many marbles, and is remarkable for the wonderful ease with which it can be worked. The Library of Congress at Washington is built of this stone.[1]

In the production of siliceous crystalline rocks, New Hampshire ranked fourth.[2] The total production of this stone in the United States for 1902 was valued at $18,257,944. New Hampshire contributed a product valued at $1,147,097, or 6.3 per cent.

The mineral industries of the state, according to Table 1, employed 1,253 wage-earners, with aggregate wages of $806,494. The wage-earners employed in the production of siliceous crystalline rocks numbered 1,219, or 97.3 per cent of the total, and their wages amounted to $791,196, or 98.2 per cent of the total.

The following table, compiled from the reports of the United States Geological Survey, shows the value of the annual production of siliceous crystalline rocks since 1887:

TABLE 3.—*Value of annual production of siliceous crystalline rocks: 1887 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Value.	YEAR.	Value.
1887	$195,000	1895	$480,000
1888	104,800	1896	497,966
1889	727,531	1897	641,691
1890	727,531	1898	683,595
1891	750,000	1899	802,636
1892	725,000	1900	870,646
1893	442,424	1901	935,494
1894	724,702	1902 [1]	1,147,097

[1] Census figures.

It will be observed that, while there has been a steady increase in value of products since 1895, previous to that date the industry experienced many fluctuations. The year 1902 was the first in which the value of the output exceeded $1,000,000.

All other minerals.—Infusorial earth and tripoli are produced in New Hampshire in small quantities. During 1902 the only deposit that was worked was on Troy mountain, in Cheshire county. The material, after it is mined, is calcined, bolted, and manufactured at Keene, by the producers of the raw material, into cleaning powders and polishers.

During 1902 Cheshire county was the only producer of mica in commercial quantities, and was credited with two operators. Mica mines have been uncovered and worked at Grafton, Grafton county; at Danbury, Merrimack county; and at Alstead, in Cheshire county. The Ruggles mine, which up to 1889 had been a constant producer since 1803, at one time contributing four-fifths of the domestic mica, was idle during 1902. While the value of the state's production of mica in 1902 was not large, the state nevertheless ranked fourth, as the entire value of the output of mica in the United States amounted to only $118,849.

The quarrying of various stones for manufacture into oilstones, whetstones, and scythestones has been an important industry in New Hampshire ever since Isaac Pike discovered a superior grit for scythestones in Grafton county in 1823.[3] The company formed to exploit the deposits now owns and operates quarries in New Hampshire, Vermont, Indiana, Massachusetts, Ohio, and Arkansas, and has mills for cutting, smoothing, and mounting the stones. Special stones of many kinds are put upon the market, and the industry shows a steady growth.[4]

During the census year there were discovered and sold a small number of beryl gems, classified as precious stones. These were all found in Grafton county and were not in any case the result of systematic search or mining.

NEW JERSEY.

Table 1 is a summary of statistics for the productive mines and quarries in the state of New Jersey for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Iron ore.	Siliceous crystalline rocks.	Clay.	Sandstones and quartzites.	Limestones and dolomites.	All other minerals.[1]
Number of mines or quarries	162	15	49	34	22	27	15
Number of operators	151	9	46	34	22	25	15
Salaried officials, clerks, etc.:							
Number	420	138	92	35	28	15	112
Salaries	$357,000	$101,870	$64,508	$26,044	$17,847	$11,301	$135,430
Wage-earners:							
Average number	5,645	1,660	947	702	418	187	1,731
Wages	$2,658,727	$773,286	$433,166	$293,232	$232,480	$80,654	$845,909
Contract work	$10,770	$10,770					
Miscellaneous expenses	$303,669	$30,114	$58,135	$19,403	$18,352	$7,833	$174,832
Cost of supplies and materials	$2,235,964	$429,231	$164,562	$67,476	$36,080	$23,044	$1,515,571
Value of product	$6,605,402	$1,228,664	$948,474	$612,721	$406,726	$188,650	$3,220,167

[1] Includes operators as follows: Cement, 2; lead and zinc ore, 1; marl, 10; slate, 1; talc and soapstone, 1.

The mineral wealth of New Jersey constitutes one of its greatest resources, and since the earliest days of its history has exerted a marked influence over its general industrial development. The most extensively utilized of the state's diversified mineral deposits is its clay, the exploitation of which has brought New Jersey into national prominence. Doubtless an important factor in their extensive development is their geographical occurrence. While brick clays are found in almost every section, nearly all the rich clays are in Middlesex county close to the navigable coast waters and the Raritan river.[1]

The metalliferous ores are mainly limited to those of iron, zinc, and copper. Lead and silver occur, and although the former has been worked, it is now abandoned, and the latter has not been found in sufficient quantities to warrant mining. The occurrence of the ores of arsenic and nickel is chiefly of mineralogical importance; no deposits or veins of workable extent have been discovered.[2]

The state from its earliest history has been an important producer of high-grade iron ore. The ore is of the magnetic variety and has a higher value per ton than that produced in any other state.[3] In 1902 the output comprised over 26 per cent of the total yield of magnetic iron ore in the country.[4] Zinc mining in the United States had its inception in New Jersey,[5] and for many years the bulk of the zinc ore mined was drawn from its deposits. The state's output of Portland cement in 1902 was approximately one-eighth of the total yield of the country. The sand deposits of southern New Jersey are of a quality that makes them valuable in the manufacture of glass, and they have been utilized for this purpose since pre-Revolutionary times.[6] The state also possesses valuable deposits of granite and sandstone that have been extensively exploited, especially during recent years. The greater part of the granite product is of crushed stone, in the output of which New Jersey exceeded every other state in 1902. Other minerals produced commercially in 1902 are marl, slate, and talc and soapstone.

In addition to these, the range of mineral deposits in the state comprises, among those of known occurrence, though not mined in 1902, the following: Asbestos, barytes, coal (bituminous), copper ores, galena, garnet, infusorial earth, magnesia hydrate and carbonate, marble, mica, plumbago, phosphate rock, sapphire, serpentine, and silver.[7]

The total expenditure for development work in 1902 was $275,950. Of this amount, $272,250 was applied to developing the cement industry. The remainder, $3,700, was expended in the development of gold and silver and iron ore deposits. Work of an experimental character was also prosecuted in connection with copper ores.

The following table shows the value of the products of manufacturing industries closely allied to or based

upon the mining industry in 1900, using as their raw material the product of the mine and quarry:

TABLE 2.—*Manufactures based primarily upon the product of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$611,748,933
Based upon the products of mines or quarries:		
Chemicals and allied products	$49,607,740	
Clay, glass, and stone products	22,767,027	
Iron and steel and their products	76,832,967	
Metals and metal products, other than iron and steel	91,855,743	
Miscellaneous industries	25,489,243	
		266,552,720
All other		345,196,213

The total value of products of the manufacturing industries based on mining was, as shown by Table 2, $266,552,720, or 43.6 per cent of the total value of the product of all manufacturing industries in the state in 1900. There were employed in all branches of manufacture in 1902, 241,582 wage-earners, who were paid $110,088,605 in wages. In 1902 the mines and quarries of the state gave employment to 5,645 wage-earners, who received $2,658,727 in wages. Comparing the figures for these two branches of industry, it is disclosed that 97.7 per cent of the wage-earners, receiving 97.6 per cent of the wages, were employed in manufacturing, while 2.3 per cent of the wage-earners, receiving 2.4 per cent of the wages, were employed in mining.

The following table shows the value of the annual production of the principal minerals in the state, 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Iron ore.	Siliceous crystalline rocks.	Clay.	Sandstones and quartzites.	Limestones and dolomites.
1890	$1,341,543	$425,673	(1)	$597,309	$129,662
1891	525,612	400,000	(1)	400,000	100,000
1892	1,388,875	400,000	(1)	350,000	180,000
1893	909,458	373,147	(1)	267,514	149,416
1894	568,056	310,965	(1)	217,941	193,523
1895	612,671	151,343	(1)	111,823	150,000
1896	528,759	204,323	(1)	126,534	134,213
1897	491,838	561,782	$258,976	190,976	141,646

[1] Not reported separately. [2] Census figures.

Iron ore.—The first recorded exploitation of the iron ores of New Jersey occurred in 1674 at Tinton Falls, near the town of Shrewsbury, in Monmouth county. The pioneer in the industry in the state was Henry Leonard, who came from the village of Rowley, in Massachusetts, to New Jersey and established the iron manufacture in that state. Bog ore was used in the first furnace. For more than a third of a century the industry of iron manufacture in the state, which grew rapidly from the start, was confined to the working of bog ore. Large quantities of iron were made from this ore at one time, and the industry of its mining and manufacture spread throughout southern and southwestern New Jersey and was for more than a century and a half an important factor in the industrial development of this part of the state. "Jersey pines" furnished the fuel for the furnaces and bloomeries, and oyster shells supplied the fluxing material.

The passing of bog ore mining was approximately coincident with the supplanting of charcoal as a fuel by anthracite coal, which took place about 1840.

The rich deposits of magnetite in northern New Jersey were discovered at an early day, and about 1710 settlements were made on Whippany river, in Morris county, for the purpose of smelting the iron ores in the neighborhood. Probably the first forge erected for the working of these magnetic ore deposits, which for almost two hundred years have been mined continuously, was located at a point about 4 miles northeast of Morristown. The celebrated Succasunna iron ore mine is near the place where the first forge was built. It was here that the pioneers in the industry obtained their ore, which was carried to the works in leather bags on pack horses; the bar iron was carried on horseback over the Orange mountains to Newark. Other forges were soon built in Morristown and some in Essex county, all of which for a long time and with the same crude methods of transportation drew their ore from the same source. The ores were free to all until the tract embracing the Dickerson mine was taken up on account of its minerals by John Reading in 1713 or 1714. The deposit has long been known as the "Dickerson mine," from one of the early governors, who was subsequently a United States Senator. On March 10, 1714, William Penn, by a warrant from the council of proprietors, acquired title to one of the richest iron ore mines in New Jersey. This tract was situated in Essex county, then Hunterdon, and was the site of what later was known as the celebrated Andover mine. The products of this mine were for many years carried on pack horses and in carts down the valley of the Musconetcong to a place on the Delaware called Durham, and thence transported by boat to Philadelphia.

For some years after the beginning of the eighteenth century New Jersey was the only colony outside of New England engaged in the manufacture of iron, and this was largely confined to its bloomeries. Not much progress was made in establishing the industry until about the middle of the eighteenth century; but from about 1740 to the Revolution many blast furnaces and other iron works were erected, and the iron industry, though hampered to some extent by restrictions imposed by England, was exceedingly active. The patriotic cause was afterwards greatly indebted for much of its iron and steel, so necessary to secure its success, to the enterprises built up between 1740 and 1770 within the borders of New Jersey. The old Oxford furnace, in

Warren county, built by Jonathan Robeson in 1742, is, according to tradition, the first one blown by a water blast. In 1880 it was still in operation, sharing with the Cornwall furnace in Pennsylvania the distinction of being the oldest furnace in the United States then in active operation.[1]

In 1790 the total production of iron ore in New Jersey was 10,000 tons. Forty years later it had increased to 20,000 tons, and in 1855 had reached a total of 100,000 tons. The output increased rapidly for almost two decades thereafter and in 1873 amounted to 665,000 tons. During the succeeding three or four years there was a marked decrease, the output in 1876 dropping to 285,000 tons. Then ensued another period of rapid increase, which continued throughout the remaining years of the decade, the maximum output in the history of the state, nearly 1,000,000 tons, being reached in 1882. During the next ten years the annual production remained steady, with only slight variations, at an average of about 500,000 tons. Between 1893 and 1897 the production reached the lowest figures since 1864, with a minimum output for the period of 257,235 tons in 1897.[2] The increase which was shown in 1898 has grown rapidly during each year since, closing with an output of 441,879[3] tons in 1902. This is a gratifying yield in view of the shortage of anthracite coal during the closing months of the year, which tended to retard the work of blast furnaces, and thus indirectly to affect the output of the mines.[2]

The iron ore producing district of New Jersey is a continuation of the ridge of Archean rock which, beginning in Putnam county, N. Y., extends southwest across Orange county, N. Y., and the Hudson river and, traversing northern New Jersey, runs out in Pennsylvania. Lenses of magnetic ore occur throughout its entire length. In New Jersey these are not as large as in the Adirondacks, but they are more regularly distributed. Four courses or mine belts are recognized in the state—the Ramapo, the Passaic, the Musconetcong, and the Pequest—in order from east to west.[4] Mining operations, which began in Morris county, have extended until at present they are widely distributed over the belt, the principal points of production being at Mt. Pleasant and Hibernia.[5]

The following table shows the annual production, in long tons, of iron ore from 1890 to 1902:

TABLE 4.—*Annual production of iron ore: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Long tons.	YEAR.	Long tons.
1890	495,808	1897	254,235
1891	525,612	1898	275,438
1892	465,455	1899	256,185
1893	356,150	1900	344,247
1894	277,483	1901	401,989
1895	282,433	1902	441,879
1896	264,999		

Siliceous crystalline rocks.—The rocks of this character have not been quarried extensively until within the last five or six years. The increase began in 1898, when the value of the output was nearly 50 per cent greater than that of 1897.[6] The maximum was reached in 1900, New Jersey then standing third among the states in the production of stones of this classification, with an output valued at more than $1,000,000.[7] The production has remained close to this figure since. The bulk of the state's yield of this classification consists of trappean rocks used principally as road materials.[6]

The belt within which occur all the granitic and gneissoid rocks enters New Jersey from New York near the Ramapo river, in Bergen county, and traverses the state in a southwesterly direction. The greatest width of the belt is less than 20 miles, while it is less than half that width at its southern extremity. Comparatively few quarries are worked throughout this area, though in many places the rocks are so situated that their exploitation is practicable at a relatively low cost. From the quarries at Dover, in Morris county, large quantities of stone for railroad construction have been taken. A good quality of granite of fine grain and even texture occurs in the Vernon valley along the eastern foot of Pochuck mountain.[8]

Clay.—The valuable clay beds of New Jersey have been known and exploited for more than a century; but their extensive occurrence and great importance to the state and the country have been understood and fully appreciated for only a comparatively short time.

The first recorded instance of clay mining in the state was in the banks of South Amboy. The clay was used in making stoneware at Van Wickle's pottery at Oldbridge, now Herbertsville, about 1800. In 1802 a second pottery was built at Sayreville, on the Raritan, and began the manufacture of stoneware from the same clay banks at South Amboy.

[6] United States Geological Survey, Twentieth Annual Report, Part VI, continued, page 279.
[7] Ibid., "Mineral Resources of the United States," 1900, page 665.
[8] Stones for Building and Decoration, by George P. Merrill, page 77 ff.

The famous fire clays of the state were first exploited after the War of 1812, probably about 1816. At about this date G. W. Price carried to Boston a boat load of fire clay, dug at Woodbridge, from the afterwards celebrated banks, and manufactured it into fire brick. Jacob Felt, about 1820, mined and carried to Boston another shipment consisting of 50 tons, for which he paid 25 cents per ton in the ground. From this beginning the mining and shipping of these clays to the same point continued for many years. In 1835 they were used in Philadelphia by Howell & Bros. in the manufacture of wall paper.

The industry of fire brick manufacture within the state had its inception in 1833, Mr. J. R. Watson, of Perth Amboy, building and operating the first plant. By this time the clay deposits were beginning to attract some attention. The Gazetteer of New Jersey stated in an issue of 1833 that "extensive beds of white pipe clay, composed principally of alumina, and infusible, have been observed between Woodbridge and Amboy." In 1840 Professor Rogers published in his final report on the Geology of New Jersey the results of a cursory examination made by him of the clay deposits, especially in the vicinity of Woodbridge, but these researches disclosed only a fraction of the full importance of the beds. During the following fifteen years the scope of the clay working industries was materially broadened. The progress is indicated by the following quotation from the State Geological Report of 1855: "Clay for making 50,000,000 fire bricks was taken out during the year from the pits at Woodbridge, Perth Amboy, and South Amboy; 2,000 tons were sold for facing paper hangings; 2,000 tons for making alum, and a considerable quantity for making fine pottery at Jersey City, Trenton, and Green Point. About 10,000 tons of stoneware clay were needed to supply the demand." Eighteen years later, in 1873, the industry of clay mining had grown to such an extent that 265,000 tons of fire clay were dug annually and sent into the market for making fire brick, fine pottery, sewer pipe, terra cotta ware, retorts, crucibles, facing for wall paper, alum, etc. The average price per ton received at that time was about $3.50.

At the same time 20,000 tons of stoneware clay were mined in the vicinity of South Amboy. This was shipped to all parts of the United States and supplied the material for the bulk of the stoneware used in the country. It brought an average price of $4 per ton.

The manufacture of fine earthenware was begun in the state in the latter fifties. In 1868 these products were turned out from 12 potteries in Trenton, and reached for the year an aggregate value of $1,500,000.

The abundance of the New Jersey clays, their superior quality, and convenience to market have made them almost essential to the successful prosecution of some of the great industries of the country.[1]

The clay wealth of the state comprises a great diversity of varieties, with characteristics that fit them for the manufacture of all the principal clay products. Except for the common brick clay of the state, which is widely distributed, the clay deposits are confined within comparatively narrow limits. The more valuable clays occur in three geographical groups. The most important is in Middlesex county, east of New Brunswick, and extends to Staten Island sound and Raritan bay. Its northern limit is a line parallel with the Pennsylvania Railroad from New Brunswick to Rahway and about 2 miles south of it, the Cheesequake creek forming its southern boundary. The district comprises an area of 68 square miles. It is within this district that the noted Woodbridge and Amboy clays, kaolins, and fire sands occur.

The second district is an extension of the first across the state and along the Delaware river southwest to Salem county, where it crosses the river and appears again in Delaware. The Trenton, Florence, and Pensauken creek clays occur in it.

The third district or group of clay deposits is within the area lying to the south and southeast of the Greensand-marl belt. The more important deposits occurring in this region are those at Conrad, in Gloucester county, and at Wheatland, in Ocean county. Of these three groups of clay deposits those of the Middlesex district are by far the most important, being superior in quality and yielding an aggregate product many times larger than that of the rest of the state combined.[2]

Clay mining as a distinct industry disassociated from the manufacture of clay products has reached a fuller development in New Jersey than elsewhere in the country, this state, in 1902, contributing almost 34 per cent of the total product of the United States.[3]

Sandstones and quartzites.—Sandstone has been quarried in New Jersey from an early date, especially in Bergen, Passaic, and Essex counties, for building purposes, and for monuments and tombstones, and has proved thoroughly durable. For many years the sandstones of New Jersey, being of finer texture and less laminated than those of Connecticut, and consequently of superior quality, have been extensively used

[1] Geological Survey of New Jersey, 1878, page 1 ff.
[2] Transactions of the American Institute of Mining Engineers, Vol. VI, page 177 ff.
[3] United States Geological Survey, "Mineral Resources of the United States," 1902, page 748.

in New York and neighboring cities as a building material.[1] Among the many notable structures built of this stone may be mentioned Trinity church, New York city.[2]

The most extensively worked stone quarries in the state are those in the belt of red or brown sandstone which extends from the New York line in a general southwesterly direction across the state to the Delaware river,[1] comprising an area of 1,540 square miles.[2]

The principal quarrying points in the belt are in various towns of Passaic, Essex, Hunterdon, and Mercer counties. The stone, like that of Connecticut, is a granitic sandstone, cemented by iron oxides, silica, and carbonate of lime, and varying in color from light brownish gray to reddish brown. The fine grained, dark brown variety is most in demand.[1]

Limestones and dolomites.—The limestones of the state are widely distributed and have been used for many years in the production of lime and cement.[3] In former years quarrying on an extensive scale was prosecuted in the outcrops of Devonian limestone at Lower Harmony, in Warren county. This limestone, known in the market as marble, was of a grayish hue and in places banded, owing to alternate lines of light and dark minerals. It was worked mainly for the Pennsylvania market. A very beautiful limestone, known commercially as "Rose Crystal Marble," has been quarried to some extent on a subordinate ridge of the Jenny Jump mountain range, in the same county. There also occurs in association with the dolomites at Montville a beautiful deep green and oil yellow, often translucent, serpentine, but it has not as yet been quarried except for cabinet specimens.[4]

All other minerals.—Among the mineral products in the output of which New Jersey takes high rank, is Portland cement. This industry has had its inception and remarkable development practically within the last decade. Although there is an abundance of limestone in the state, it was thought for many years, in fact until quite recently, that very little, if any, of it was adapted to the manufacture of cement. Indeed, this was the opinion expressed by the state geologist in 1868, formed after an exhaustive study of the various limestones of the state.[3]

Prior to 1892 the production of Portland cement in the state was not recorded by the United States Geological Survey. Beginning in 1892 with a reported output of 20,000 barrels, it increased during the following year by 300 per cent to 60,000 barrels. The rapid growth of the industry continued through all the succeeding years of the decade, until in 1902 the total yield was 2,152,158 barrels, or more than 100 times the output of 1892. The following table shows the annual production of Portland cement since 1892:

TABLE 5.—*Annual production of Portland cement: 1892 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Barrels.	YEAR.	Barrels.
1892	20,000	1898	587,163
1893	60,000	1899	892,167
1894	72,223	1900	1,169,212
1895	155,000	1901	1,612,000
1896	247,100	1902	2,152,158
1897	430,335		

The raw materials used in the manufacture of Portland cement occur in many localities in Sussex and Warren counties, and to a limited extent in Hunterdon county. The areas of principal importance are in the Kittatinny valley and in some of the inter-Highland valleys.[5]

Zinc ore mining in the United States began in Sussex county, N. J., in 1838. The ore, which was of the red variety, was taken to the Government arsenal at Washington, where it was reduced, and the zinc used in the brass designs of the standard of weights and measures ordered by Congress. The process used, however, was too costly to permit commercial production of the metal.[6] In 1848 the New Jersey Zinc Company was organized and erected at Newark an extensive plant for the reduction of the metal. By 1852 the industry had made considerable headway, 860 tons of metallic zinc being produced. In 1853 the output increased to 1,440 tons, and for some years the state was the only producer of zinc in the country.[7]

The zinc deposits of the state occur in Sussex county on a range of hills which commences near Sparta and extends in a southerly direction through Stirling to Franklin.[8] The points of principal production have been Ogdensburg and Franklin.[2]

The marls of New Jersey have been dug for use as fertilizers since the early history of the state. The marl, or Greensand region, is in the southern part of the state, and is comprised within a belt from 6 to 15 miles in width, extending from the ocean below Sandy Hook across the state to the Delaware.[9]

The quarrying of roofing slate in New Jersey dates from about 1823, when it is believed the first quarry was opened by Mr. Evans, near the Delaware Water-gap. The slate deposits of the state are extensive and occur mainly within a belt entering the state from Pennsylvania and extending entirely across the northern part of the state to the New York state line, and along the northwestern border of Kittatinny valley for a distance of about 35 miles.[10]

The state's production of soapstone in 1902 was obtained from Warren county.

NEW MEXICO.

Table 1 is a summary of the statistics of the productive mines and quarries of the territory of New Mexico for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Gold and silver.	Copper.	Precious stones.	Sandstones and quartzites.	All other minerals.[1]
Number of mines or quarries	161	30	91	17	8	7	8
Number of operators	207	25	91	17	60	7	7
Salaried officials, clerks, etc.:							
Number	175	68	75	24	3		5
Salaries	$209,569	$85,599	$80,390	$32,120	$5,160		$6,300
Wage-earners:							
Average number	2,275	1,439	519	164	36	8	109
Wages	$1,646,833	$1,027,460	$409,779	$128,483	$22,087	$6,515	$52,509
Contract work	$48,381	$5,770	$32,345	$10,266			
Miscellaneous expenses	$140,055	$63,990	$34,110	$26,858	$1,900	$536	$12,661
Cost of supplies and materials	$497,949	$156,513	$256,816	$49,408	$2,480	$370	$32,362
Value of product	$2,686,473	$1,500,230	$677,168	$271,270	$51,600	$12,291	$173,914

[1] Includes operators as follows: Graphite, 1; iron ore, 1 (2 mines); lead and zinc, 1; marble, 2; mica, 1; phosphate rock, 1.

Doctor Wizlizenus, writing in 1847, gives a concise presentation of the mineral resources of New Mexico. "In Spanish times several rich mines were worked at Avo, at Cerrillos, and in the Nambe mountains, but none at present. Copper is found in abundance throughout the country, but principally at La Tijera, Jemez, Abiquiu, Guadalupita, etc.; iron, though also abundantly found, is entirely overlooked. Coal has been discovered in different localities, as in the Raton mountains, near the village of Jemez, southwest of Santa Fe, and near, but south of, Placer mountain. Gypsum, both common and selenite, is found in large quantities, extensive layers of it existing in the mountains near Algodones, on the Rio Grande, and in the neighborhood of the celebrated salinas. It is used as common lime for whitewashing, and the crystalline or selenite instead of window glass. About 100 miles south-southeast of Santa Fe, on the high table-land between the Rio Grande and Pecos, are some extensive salt lakes, or salinas, from which all the salt (muriate of soda) used in New Mexico is procured."[1] Very little mining was done by the Americans for many years after their occupation of the territory.[2]

Aside from the minerals commercially produced in 1902, deposits of alum and sulphate of alumina, cinnabar, molybdenum, tungsten, vanadium, and serpentine are known to occur in the territory.

In addition to the productive mining there were 159 operators engaged in developing 159 mines and wells, of the following character: Gold and silver, 156; petroleum, 2; and coal, 1. They gave employment to 358 wage-earners, who were paid $270,896 in wages. Other expenses were contract work, $73,128; miscellaneous expenses, $34,125; and the cost of supplies and materials, $128,488.

The following table shows the value of the products of all the manufacturing industries of the territory, as reported at the census of 1900, and the products of the manufacturing industries which chiefly utilize, as raw materials, the products of mines and quarries:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$5,605,795
Based upon the products of mines or quarries:		
Clay, glass, and stone products	$114,698	
Iron and steel and their products	65,546	
Metals and metal products, other than iron and steel	1,100,995	
Miscellaneous industries	556,247	
		1,837,486
All other		3,768,309

The manufactured products thus based upon the products of mines and quarries constitute 32.7 per cent of the total value. The value of the mineral production of the territory in 1902 was $2,686,473, or 32.4 per cent of the value of the combined product of manufac-

[1] Mineral Resources of the United States, by Browne and Taylor, 1867, page 325.

[2] History of the Pacific Coast States, by Hubert H. Bancroft, Vol. XII, page 748.

tures and mines and quarries of the territory. Mines and quarries in 1902 employed 2,275 wage-earners, who were paid $1,646,833 in wages. In 1900 manufactures gave employment to 2,600 wage-earners, who were paid $1,350,586; therefore manufactures gave employment to 53.3 per cent of the wage-earners and paid 45.1 per cent of the wages, while mines and quarries gave employment to but 46.7 per cent of the wage-earners and paid 54.9 per cent of the wages.

The following table, compiled from reports of the United States Geological Survey, shows, with the exception of copper ore, values for which can not be obtained, the value of the annual production of the principal minerals of the territory from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Gold.[1]	Silver.[1]	Sandstones and quartzites.
1890	$504,390	$850,000	$1,680,808	$186,804
1891	779,018	905,000	1,713,131	50,000
1892	1,074,601	950,000	1,521,390	20,000
1893	979,044	913,100	592,679	4,922
1894	935,857	829,519	276,764	300
1895	1,072,520	492,200	898,320	2,700
1896	930,381	475,800	889,277	(2)
1897	991,611	356,500	697,535	(2)
1898	1,344,750	539,000	549,883	3,500
1899	1,461,865	584,100	650,731	1,829
1900	1,776,170	832,900	[3]269,266	2,500
1901	1,546,652	688,400	[3]338,040	(2)
1902[4]	1,500,230	531,100	[3]242,316	12,291

[1] Estimates of the Director of the Mint, value of refined product, silver at coining value. The values given in Table 1 are the values at the mine.
[2] Not reported separately.
[3] Commercial value.
[4] Census figures except for gold and silver.

Coal, bituminous.—The production of coal in New Mexico was first reported for 1882, when it amounted to 157,092 short tons. It was then mined in Raton, Cerillas, Gallup, Monero, and San Pedro counties, which represent the present counties of Colfax, Santa Fe, McKinley, and Rio Arriba. In addition to these counties coal is now mined in Lincoln, San Juan, San Miguel, and Socorro counties. McKinley and Colfax counties are the heaviest producers, their product being over 74 per cent of the total tonnage of the territory. The coals range from lignite to anthracite, considerable quantities of the latter being found associated with bituminous coal in the Cerillos district.

The following table, compiled from reports of the United States Geological Survey, shows the annual production of coal from 1882 to 1902:

TABLE 4.—*Annual production of coal, bituminous: 1882 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.
1882	157,092	1893	665,094
1883	211,347	1894	597,196
1884	220,557	1895	720,654
1885	306,202	1896	622,626

1887	508,034	1898	992,288
1888	626,665	1899	1,050,714
1889	486,943	1900	1,299,299
1890	375,777	1901	1,086,546
1891	462,328	1902	1,048,763
1892	661,330		

Gold and silver.—The Old Placer gold mines, 30 miles southwest of Santa Fe, were discovered in 1828, and were worked to a considerable extent by the Mexicans in the early days. The New Placer gold mines were discovered in 1839.[1] Silver was discovered at Georgetown in 1872.[2] The rich Lake Valley silver mines commenced producing in 1881. The "Bridal Chamber" at Lake Valley, a cavern in the limestone lined with rich silver ores, was one of the most remarkable ore deposits ever found. It was here that Governor Safford offered $50,000 for the ore he could extract unaided in ten hours.[3]

The decade 1880 to 1889 witnessed a large increase in the gold and silver production, as shown by the following table, compiled from the reports of the Director of the Mint:

TABLE 5.—*Annual production of gold and silver: 1880 to 1889.*

[Reports of the Director of the Mint.]

YEAR.	Gold.	Silver.[1]	YEAR.	Gold.	Silver.[1]
1880	$49,354	$372,337	1885	$800,000	$3,000,000
1881	185,000	275,000	1886	400,000	2,300,000
1882	150,000	1,800,000	1887	500,000	2,300,000

1884	300,000	3,000,000	1889	1,000,000	1,461,010

[1] Coining value.

Copper.—Two copper mines were extensively worked before the Civil War—the Santa Rita and the Hanover—turning out about 12 tons of copper per week and employing jointly about 500 hands.[4] The Santa Rita mines, near Silver City, were discovered by Lieutenant-Colonel Carrisco in 1800,[5] and were extensively worked for copper, much of it native, before the Gadsden Purchase.[6]

TABLE 6.—*Annual production of copper: 1882 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Pounds.	YEAR.	Pounds.
1882	869,498	1893	280,742
1883	823,511	1894	31,884
1884	59,450	1895	143,719
1885	79,839	1896	2,701,664
1886	558,385	1897	701,892
1887	283,664	1898	1,592,371
1888	1,631,271	1899	3,935,441
1889	3,686,137	1900	4,169,400
1890	850,034	1901	9,629,884
1891	1,233,197	1902	6,614,961
1892	1,188,796		

Precious stones.—The production classified as precious stones consists of turquoise, from Grant and Otero counties, and garnets, from McKinley county. The value of the turquoise product in 1902 was $51,100, of which $47,600 was from the mines of Grant county and $3,500 from Otero county. The garnets from McKinley county were found by individuals, and were not from any regularly operated mine.

[5] Harper's Encyclopedia, Vol. IX, page 448.
[6] The Mineral Industry, 1894, Vol. III, page 247.

The most interesting of the ancient turquoise workings are in the Chalchuitl mountain ("Chalchuitl" is the Indian name for turquoise). The entire hill is undermined by caves, and there are two immense open cuts, the larger being over 300 feet across and 200 feet or more in depth. According to tradition, a great rock slide occurred here in 1680 that buried some twenty-five Indians. The requisition of the Spaniards on the neighboring pueblo of San Marcos for more Indians to take the place of those entombed led to a general uprising, that resulted in driving the Spaniards out of the country.

Modern turquoise mining in New Mexico has been developed since the census of 1890. There are three districts where turquoise is produced—the ancient turquoise mines in the Cerrillos mining district, 18 miles south of Santa Fe, a locality in the vicinity of Cow Springs mountain and Burros, and the mines opened a few years ago in the Jarilla district, in Otero county. In opening the old workings of the ancient mines stone hammers and pottery in considerable quantities were found.[1]

For the decade from 1890 to 1900 the total output of the largest turquoise mine at Cerrillos amounted to more than $2,000,000 in value. A single stone has been sold for as much as $3,000.

Pyrope garnets, sometimes called Arizona rubies, are found on the Navajo reservation. An interesting variety of green semiopal has been discovered in Taos county.

Sandstones and quartzites.—Sandstone quarries are operated in Bernalillo, Colfax, and San Miguel counties, chiefly for building stone. In the vicinity of Las Vegas, Hot Springs, and Albuquerque occur beds of light gray, brown, and pink sandstone of fine texture.[2]

[1] Report of the Governor of New Mexico, 1901, page 405.
[2] Stones for Building and Decoration, by George P. Merrill, page 149.

All other minerals.—Amorphous graphite is found in the Raton mountains. The total graphite production of the territory was refined graphite from one establishment, an incorporated company, operating in Colfax county.

One individual operator worked two iron mines in 1902 in Grant county. The deposits of iron ore in the territory are numerous, extending from the Raton mountains to the Placer and Sandia mountains. Ore of excellent quality is found near Las Vegas. At the Hanover copper mine there is a heavy supply of iron ore, partly magnetic and partly a red hematite. On the Rio Puerco, associated with coal, occur frequent bands of iron ore. East of the Gallinas range and about 30 miles west of Socorro, in Socorro county, there is a large tract of land covered with iron nodules that have been shipped in large quantities for use as flux in smelters. Good iron ore occurs also in the Santa Rita, Burros, and other ranges in the southern part of the territory.[3]

Marble was quarried in 1902 at two quarries in Otero county. Near the Rio Puerco station of the Atlantic and Pacific Railroad, in Valencia county, are deposits of travertine, or stalagmitic matter, thus far exploited only in a preliminary way. The stone varies in color from almost white to almost black, and from translucent to opaque. The better varieties show, when polished, a silky luster and a radiated fibrous structure.[4] White and black marble occurs in the White Oaks district, Lincoln county.

Mica was obtained from one mine in Taos county. It has also been worked to some extent in the Cribbenville district, Rio Arriba county.[5] Phosphate rock was reported for the first time as mined to a small extent in Luna county.

[1] Includes operators as follows: Clay, 7 (8 mines); crystalline quartz, 1; feldspar, 1; flint, 2; infusorial earth, tripoli, and pumice, 1; lead and zinc ore, 1; mineral pigments, crude, 5; sulphur and pyrite, 1.

The mineral resources of the state are varied, 23 different minerals contributing to the state's output in 1902. Among the various branches of the mining industry in the state the manufacture of cement is foremost. Both natural rock and Portland cement are produced in large quantities; and New York has led the states for many years in the production of natural rock cement. The greater part of the crystalline graphite production in the United States comes from the mines at Ticonderoga, in Essex county, where the mineral has been mined for nearly a century. The gypsum deposits of the state are extensive, and in gypsum mining New York ranks fourth. The glass sand found in the state occurs in a form sufficiently disintegrated to require no further crushing before using it in the manufacture of glass.[1] The corundum and emery mines near Peekskill are among the largest producers of these abrasive materials in the United States, and in the production of garnet for abrasive purposes the state ranks high. Most of the buhrstones made in the United States are from the quarries of the state along the eastern slopes of the Appalachian mountains. The state for many years has been a large producer of fibrous talc, most of which is used in paper making. Extensive deposits of clays are widely scattered and many of them are capable of being used in the manufacture of terra cotta, roofing tile, and the coarser grades of pottery.[2] Natural gas is also found over a very large area of the state. It was first used as a source of light and heat at Fredonia, Chautauqua county, in 1821.[3] The oil territory in New York is a continuation of the Bradford, Pa., field and has been more or less productive since 1865.[4] With the exception of Pennsylvania, New York state is the largest producer of the magnetite variety of iron ore, which

[2] New York State Museum, Bulletin No. 12, page 98.

[3] United States Geological Survey, "Mineral Resources of the United States," 1902, page 648.

[4] New York State Museum, Bulletin No. 15, page 558.

abounds in the Highlands of the Hudson and in the Adirondack region, where the ore has been mined for over a century in the Lake Champlain valley.[1] Iron ores of both the red and brown hematite variety are also mined in the state, and in a number of localities ore of the hematite variety is found suitable for metallic paint, and is also used for coloring matter in making mortar.

The numerous quarries of the state produce annually large and valuable quantities of fine stones, among which are included the granite of the Adirondack region, the sandstones of Potsdam and Medina, the bluestone of the Hudson valley, the shell limestone of Lockport, the black marble of Glens Falls, the red marble of Warwick, the verd antique of Moriah, the roofing slate of Washington, Rensselaer, and Columbia counties, and the white marble of Westchester.[2]

Other minerals mined or quarried in the state in greater or less quantities are crystalline quartz, feldspar, flint, infusorial earth, lead and zinc ore, and sienna.

The following minerals also occur in the state, but were not produced in commercial quantities in 1902: Barytes, chrysoberyl, copper, fluorite, ilmenite, manganese, molybdenum, monazite, nickel, pyrope, rutile, serpentine, strontium ore, whetstones, mica, tourmaline, and sulphur and pyrite.

In addition to the productive mines, quarries, and wells shown in Table 1, 6 operators reported mines and quarries having no production, the work done during 1902 being confined to development and care. These operators gave employment to 96 wage-earners on an average during the year and paid $50,403 in wages. The 11 salaried officials, clerks, etc., received $16,569; the contract work amounted to only $500; the miscellaneous expenses were $6,131; and the cost of supplies and materials was $2,164.

The following table shows the value of the products of manufacturing industries based primarily upon minerals mined or quarried, as well as the value of all manufactured products of the state as reported at the census of 1900:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$2,175,726,900
Based upon products of mines or quarries:		
Chemicals and allied products	$58,870,609	
Clay, glass, and stone products	42,594,874	
Iron and steel and their products	157,050,481	
Metals and metal products, other than iron and steel	93,341,219	
Miscellaneous industries	140,844,342	
		492,701,525
All other		1,683,025,375

The value of the manufactured products, based primarily upon minerals mined and quarried, as shown by the foregoing table, amounted to $492,701,525, or 22.6 per cent of the total value of all manufactures in the state as reported for 1900. The value of the output of the mines, quarries, and wells of the state in 1902, $13,350,421, was six-tenths of 1 per cent of the total value of all the manufactures of 1900, and the products of mining and quarrying in 1902.

The wage-earners employed during the census year 1900 by the manufacturing industries of New York state numbered 849,056, and the wages paid amounted to $408,855,652. The operators of the mines, quarries, and wells of the state reported that they employed, during 1902, 9,560 wage-earners and paid $5,099,753 in wages. Manufactures and mining together gave employment during the year to 858,616 wage-earners and paid $413,955,405 in wages. Manufactures, therefore, employed 98.9 per cent of the wage-earners and paid 98.8 per cent of the wages, and mines and quarries gave employment to but 1.1 per cent of the wage-earners and paid 1.2 per cent of the wages.

The following table presents the value of the annual production of the leading minerals of the state from 1890 to 1902:

[1] New York State Museum, Bulletin No. 15, pages 529 to 535.
[2] King's Handbook of the United States, page 589.

[1] Values of Portland cement previous to 1894, and of natural rock cement previous to 1893 include cost of packages.
[2] Value not reported.
[3] Census figures.
[4] Included in natural rock cement.

Cement.—New York, which leads the states in the manufacture of the Rosendale, or natural rock cement, is also the state in which the industry in this country was first established. Natural-cement rock was first discovered in this country about 1818 at or near Chittenango, Madison county, N. Y., and was first used in the construction of the Erie canal.[1] In 1823, when the Ulster county section of the Delaware and Hudson canal was under construction, hydraulic-cement rock was discovered near Rosendale.[2] In 1825 a rock similar to the Chittenango variety was discovered at Highfalls, in Ulster county, and the first crushing mill was erected there in 1826. In 1828 a mill was built at Rosendale, in Ulster county. This locality soon became the leading center for this industry, and has so remained.[3] Extensive works were also erected at Whiteport and at other places in the vicinity.

Upon the completion of the canal activity in the manufacture of cement greatly declined, but upon the reopening of the old Snyder mill interest revived and the natural rock cement was made for the general market. Since 1839, when an exceptionally high grade of cement rock was found at Akron, in Erie county, an increasing industry has been maintained in that region.[3]

Certain strata of limestone were found near South Rondout, Ulster county, that are well adapted to the manufacture of Portland cement, and suitable clay for its production was also found near Phoenicia, in the same county.

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of both Portland and natural rock cement from 1890 to 1902:

TABLE 4.—*Annual production of cement: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Portland (barrels).	Natural rock (barrels).	YEAR.	Portland (barrels).	Natural rock (barrels).
1890	65,000	3,766,756	1897	394,398	4,259,186
1891	87,000	3,931,306	1898	554,358	4,157,917
1892	124,000	3,780,687	1899	472,386	4,689,167
1893	137,096	3,597,758	1900	465,832	3,409,085
1894	117,275	3,446,330	1901	617,228	2,234,131
1895	159,320	3,939,727	1902	1,156,807	3,577,340
1896	260,787	4,181,918			

In 1902 a total of 21 plants in the state were making cement, 11 of which manufacturing natural rock cement only, 8 making Portland cement only, and 2 making both. The total output was 4,734,147 barrels, valued at $3,656,589. Of this output 3,577,340 barrels were natural rock cement and 1,156,807 Portland cement. Ulster county alone produced 2,730,750 barrels of natural rock cement, or 76.3 per cent of the total for the state.

Limestones and dolomites.—The limestones in the state that furnish building stone belong to the following named formations: Calciferous, which may be traced along the Mohawk valley, in Herkimer, Montgomery, and Oneida counties; the Chazy, seen in Clinton county in its typical development and in the Champlain valley; the Trenton, found in Montgomery, Fulton, Herkimer, Oneida, Lewis, Jefferson, St. Lawrence, Hamilton, Clinton, Essex, Warren, and Saratoga counties; the Niagara, which has its greatest development near the Niagara river; the Lower Helderberg, found in the Rondout valley and in Ulster, Greene, Herkimer, and Otsego counties; the Upper Helderberg, found in Onondaga, Cayuga, Seneca, Monroe, Genesee, Erie, and Ulster counties; and the Tully, found in Onondaga county. A stratum of Lower Silurian limestone, 60 to 70 feet in thickness, is extensively worked for ornamental and building purposes at Greenport, Columbia county. It is a stone of medium texture, semicrystalline, highly fossiliferous, of a water-blue or gray color, and has been known as "coal-shell marble." In various towns in Montgomery county a gray or blue-gray semicrystalline limestone is quarried for building material.[4] The Onondaga gray limestone is well developed and is extensively quarried in Onondaga county. The Upper Helderberg beds at Auburn, Cayuga county, have furnished gray and blue-gray magnesian limestone since 1810, when the first quarry was opened. The Lockport gray limestone has been quarried in Niagara county along the Erie canal since 1825.[5]

The 181 quarries from which a production was reported in 1902 were located in 34 counties, and had an aggregate output valued at $2,503,536, New York thus taking fifth place among the states in the production of limestone. The increase over 1901 amounted to $764,820. The value of the limestone quarried for building purposes in 1902 amounted to $480,141.

Petroleum.—The occurrence of petroleum in New York state was first recorded by a Jesuit missionary who visited the oil spring at Cuba, Allegany county, in 1627. The Indians valued the oil from this spring for its supposed curative powers when externally applied, and it became widely known as "Seneca oil."[6] The oil territory in the state is a continuation of the Bradford field of Pennsylvania, and almost all the developed territory in the state is contained in Cattaraugus and Allegany counties, in the southwestern part of the state. The first drilling was done at Limestone, in Cattaraugus county, in 1865. In 1881 a well was drilled at

[6] Ibid., pages 557 and 558.

Petrolia, in Allegany county, and a year later another was drilled at Richburg, in the same county. The oil varies in color from light yellow to almost black, although the dark green oil is by far the most abundant.[1]

In 1902 there were 8,443 producing wells, with an output of 1,119,730 barrels, valued at $1,530,852. This was a decrease in production of 86,888 barrels as compared with 1901.

The following table, compiled from the reports of the United States Geological Survey, shows the annual petroleum production of the state from 1891 to 1902:

TABLE 5.—*Annual production of petroleum: 1891 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Barrels.	YEAR.	Barrels.
1891	1,585,030	1897	1,279,155
1892	1,273,343	1898	1,205,250
1893	1,031,391	1899	1,320,909
1894	942,431	1900	1,300,925
1895	912,948	1901	1,206,618
1896	1,205,220	1902	1,119,730

Sandstones and quartzites.—The principal sandstones quarried in New York state may be divided into three groups, belonging respectively to three distinct geological horizons, and each group having its peculiar characteristics.[2]

The first group, popularly known as "bluestone," belongs to the Hamilton period of the Devonian formations. The stones are fine grained, compact, dark blue-gray stones, very strong and durable.[2] The area in which bluestone is quarried in the state extends from the west shore of the Hudson river, in Albany, Greene, and Ulster counties, in a southwesterly direction to the Delaware river, through Delaware and Sullivan counties. There is also a small isolated region of production in Chenango county.[3]

The second group belongs to the Medina period of the Upper Silurian formations. The stones are largely siliceous, of coarser, more distinctly granular texture than the bluestone, and are gray or red in color. Quarries of Medina sandstone are found in Oswego, Oneida, Cayuga, Wayne, Monroe, Orleans, and Niagara counties. The stone has been quarried at Lockport, in Niagara county, since 1824.[4] This stone has a wide use for street paving, in place of the usual granite or trap blocks.[2]

The third group belongs to the Potsdam period of the Cambrian formations, the oldest formation in which sandstone is quarried for building purposes in the state. The Potsdam sandstone is quarried in Jefferson, Franklin, Essex, Washington, and St. Lawrence counties. The most extensive openings are near Potsdam, in St. Lawrence county, the stone being hard, compact, and even grained, and pink to red in color. Some of it has a laminated structure and striped appearance. It is an excellent building stone, and is widely known and esteemed for its beauty and durability.[5]

The value of the sandstone quarried in the state in 1902 at the 377 productive quarries amounted to $1,408,699, an increase over 1901 of $77,372. The value of the stone quarried for building purposes amounted to $550,039; for paving, $264,858; for curbing, $272,831; and for flagstones, $230,158. The productive quarries were located in 31 counties; Orleans ranking first in value of product.

Iron ore.—Albany, Cayuga, Clinton, Columbia, Dutchess, Essex, Franklin, Herkimer, Jefferson, Lewis, Madison, Oneida, Onondaga, Orange, Putnam, Richmond, Rockland, St. Lawrence, Saratoga, Warren, Washington, Wayne, and Westchester counties are known to contain one or more of the varieties of iron ore found in the state, and in most of these counties iron ore has been mined at one time or another.[6]

Although iron ore was found in various places by the Dutch during their rule from 1614 to 1664, no known effort was made by them to manufacture iron, and it is not probable that any mining of iron ore of consequence was then attempted. The first known ironworks in the state were established in Columbia county, near the Connecticut line, about 1740, but the ore was mainly obtained from the Salisbury mine in Litchfield county, Connecticut.

With the discovery of the celebrated Sterling mine, near Monroe, in Orange county, in 1750, and the building of a furnace in that locality in the succeeding year, iron ore mining in New York state may be said to have really begun.[7] The Forest-of-Dean mine, 5 miles west of Fort Montgomery, in Orange county, was discovered about the same time.[8]

Historic interest attaches to the Sterling group of mines, not only because here was probably the first iron mine opened in the state but also because the anchors for the United States frigate *Constitution*, and the great iron chain suspended across the Hudson river at West Point in 1778 to prevent the passage of the British vessels, were made at the Sterling Iron Works from ores produced at these mines.[7]

The Maltby mine, near Millerton, in Dutchess county, opened in 1750, has produced a large amount of ore, and much of it was smelted in a furnace on the property.[9] The Armenia mine, in Dutchess county, opened about 1760, was still worked in 1902. During the Revolution the ore from this mine was used for mak-

[9] Ibid., page 58.

ing guns.[1] The output from the Dutchess county iron ore mines at the present time is comparatively small.

Iron ore was mined and furnaces were erected in Westchester county before the close of the eighteenth century, and iron mines were also worked in Putnam county about the same time.[1] The Tilly Foster mine is located near Brewster, in Putnam county. Neither Westchester nor Putnam county reported production in 1902.

About 1800 the celebrated Champlain iron district, comprising the counties of Essex, Clinton, and Franklin, was developed,[1] one of the oldest openings in Essex county being the Castaline bed, near Elizabethtown.[2] The output during the earlier years of the development was small, aggregating but a few thousand tons, but it increased rapidly after 1840, and in 1868 the town of Moriah alone produced 230,000 tons.[3] With the further development of the Port Henry and Chateaugay mines this district was and is to-day the leading iron ore producing district in the state.[4]

The Caledonia mine at Rossie, St. Lawrence county, was opened in 1812, the Kearney in 1825, and the Keene in 1837. These mines produced ore of the red hematite variety.[5] The Old Sterling mine, near Antwerp, in Jefferson county, first opened in 1836, is another mine that produces red hematite ore.[6] This mine was in operation in 1902.

The Clinton, or fossil, ores have been found in Herkimer, Oneida, Madison, Cayuga, Wayne, and Monroe counties, but very little mining has been done except in the towns of Clinton, in Oneida county, and Ontario, in Wayne county. The first lease for digging Clinton ore was given in 1797.[7]

In 1902 there were 15 productive iron mines in the state, in Clinton, Dutchess, Essex, Herkimer, Jefferson, Lewis, Oneida, Orange, St. Lawrence, and Wayne counties. The total production was 555,321 long tons, valued at $1,362,987. Essex county alone produced 324,731 tons. Magnetic ore was produced in Essex, Clinton, Herkimer, Lewis, and Orange counties; red hematite in Jefferson and St. Lawrence counties; fossil in Wayne and Oneida counties; and brown hematite in Dutchess county.

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of iron ore in New York state from 1884 to 1902:

1893	534,122		

[1] Quantities reported for the first five years represent the output of the leading districts.

Siliceous crystalline rocks.—Although massive crystalline rocks are of common occurrence in the state, they do not outcrop over extensive areas, excepting in the Adirondacks and in the Highlands of the Hudson. Gneissic rocks have been quarried at many points within the city limits of New York. In Westchester county there are belts of gneiss and mica schist. Granite quarries have been opened in Putnam, Orange, and Rockland counties.[8]

Probably the most important of the true granites of the state for monumental work is the red variety quarried in various places on Grindstone Island, Jefferson county, in the St. Lawrence river. The stone is deep red and coarsely crystalline, taking a high lustrous polish.[9]

In 1902 granite was quarried in Clinton, Fulton, Herkimer, Jefferson, Orange, Putnam, Richmond, Rockland, St. Lawrence, and Westchester counties. The 22 productive quarries had an output valued at $651,014, of which Westchester county was credited with $302,526. The value of the granite, both rough and dressed, quarried for building purposes was $307,453, and of that dressed for monumental work was $7,180.

Talc and soapstone.—The fine deposits of soapstone in the vicinity of Gouverneur, in St. Lawrence county, attracted the attention of a mineralogist prospecting in that county during the seventies. Later, attention was directed to the rich deposits of foliated talc in the town of Fowler, but it was found that the material was not suitable for the uses contemplated. About this time workmen engaged in roadmaking in the vicinity of Gouverneur found a large vein of fibrous talc, the first of this variety discovered which, when pulverized, was found to be a suitable material for weighting and finishing paper. Prospecting was carried on, new mines were opened, and new mills erected, and by 1893 every

[8] New York State Museum, Bulletin No. 15, page 374.
[9] Stones for Building and Decoration, pages 78 and 79.

available water privilege from Talcville down the Oswegatchie to a point below Gouverneur was occupied by a milling establishment devoted to the production of pulverized talc.[1]

All the mines that have been developed are found on a comparatively narrow ridge, about 7 miles long, the most valuable deposits being in the immediate vicinity of Talcville. Here the best beds are of unknown depth and extent. In most of the mines to the south of Talcville the fibrous material is too largely mixed with the foliated talc to be valuable. At the Freeman mine active operations are carried on 300 or 400 feet below the surface, the deposit being of vein form and having well-defined granitic walls. The material as it comes out in the form of slabs is easily split in the direction of the fiber, but is quite refractory across the grain. The slabs have a pure, pale, sea-green tint, while the manufactured product is snow-white. The principal use of fibrous talc is in filling and weighting paper, but it is also used as an adulterant in certain drugs and as a mixer in cheap grades of soap.[1]

In 1902 there were 4 productive mines in St. Lawrence county, the total output being 71,100 short tons, valued at $615,350.

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of fibrous talc in the state from 1880 to 1902:

TABLE 7.—*Annual production of talc and soapstone: 1880 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.
1880	4,210	1892	41,925
1881	5,000	1893	35,861
1882	6,000	1894	39,906
1883	6,000	1895	39,240
1884	10,000	1896	46,089
1885	10,000	1897	57,009
1886	12,000	1898	54,356

1889	23,746	1901	69,200
1890	41,354	1902	71,100
1891	53,054		

Marble.—Crystalline limestones occur in New York city and in Westchester county, in the Highlands of the Hudson, and in the Adirondack region. Quarries opened in Westchester, Putnam, and Dutchess counties have yielded a large amount of fine white marble.

Marble has been taken from quarries at Tuckahoe, in Westchester county, since 1820.[2] The stone is pure white in color and somewhat irregular in quality, but the better grades are highly esteemed for architectural purposes and have been used in some of the finest buildings in New York city.[3]

The Gouverneur marble, in St. Lawrence county, is a very coarsely crystalline light gray magnesian limestone, which although too coarse for carved work is suitable for massive structures. It is also used largely for monuments, as well as for building and ornamental work, because it retains a good surface and polish and is believed to be durable.[3]

In the Lower Silurian formation at Plattsburg and Chazy, in Clinton county, two excellent varieties of colored marbles occur, which are commercially known as "Lepanto" and "French gray." The French gray has been used more extensively, with the possible exception of the Tennessee marble, than any other domestic marble for mantels, table tops, tiling, and general interior decorative work.[3]

At Glens Falls, in Warren county, there is an extensive deposit of dark blue-black magnesian limestone, certain strata of which furnish the finest varieties of black marble at present quarried in this country. The stone is very fine grained and compact, and when polished is a deep, lustrous black in color, though the uniformity of the color is sometimes broken by the presence of a small white fossil.

A beautiful coarsely crystalline marble of a carmine-red color, sometimes slightly mottled or veined with white, is found at Warwick, in Orange county. This stone has been but little used, and the supply reported is small.

A peculiar granular stone, consisting of an intimate mixture of serpentine, dolomite, and calcite, interspersed with small flecks of phlogopite, has been quarried at Moriah and Port Henry, in Essex county, under the name of ophite marble. This stone is nearly free from the numerous dry seams and joints that prove so objectionable in most serpentines, and it can be obtained in sound blocks of fair size. The stone polishes well and is said to be durable. A stone of the same general nature has been quarried near Thurman,[4] in Warren county, and it occurs elsewhere in the same county.

The largest and most valuable deposit of serpentine in the state is at Gouverneur, Fowler, and Edwards, in St. Lawrence county. The rock is massive and sound and remarkably free from the defects usually developed in rocks of this class. Near Pitcairn, in the same county, there is a fine deposit of serpentine of the variety commonly called precious, and serpentine, from almost black to nearly white, forms the main range of hills on Staten Island.[5]

The producing marble quarries of the state in 1902 numbered 14, and were located in Clinton, Columbia, Dutchess, St. Lawrence, Warren, and Westchester counties. The value of the marble quarried amounted to $577,298, an increase over 1901 of $198,139. Of the total, $267,013 was the value of the marble dressed for

[5] Ibid., page 368.

building, while that dressed for monumental work was valued at $143,080.

Natural gas.—Over a very large area in the western part of the state natural gas is found in a number of different sandstones and limestones. Along the southern shores of Lake Ontario and Lake Erie are scattered a vast number of small wells, each furnishing gas to from one to four families.

In 1902 there were 612 productive gas wells in the state, producing an output valued at $346,471, an increase of $53,199 over 1901.

Gypsum.—The gypsum deposits extend in a narrow belt through the central part of the state in Madison, Onondaga, Cayuga, Ontario, Monroe, Livingston, and Genesee counties. The bed near Union Springs, in Cayuga county, was first opened in 1828.[1] In a number of places the industry is only of local importance, the product being used exclusively for land plaster, but there are some large plants which produce principally wall plaster.

In 1902 the 17 productive plants produced 95,318 short tons, of which 60,184 was calcined into wall plaster and plaster of Paris. The entire product was valued at $259,170; that calcined into wall plaster at $200,236. The state ranked fourth among the states in the production of this mineral.

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of gypsum in New York state from 1889 to 1902:

TABLE 8.—*Annual production of gypsum: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.
1889	52,608	1896	23,325
1890	32,903	1897	33,440

1892	32,394	1899	52,149
1893	36,126	1900	58,890
1894	31,798	1901	119,565
1895	33,587	1902[1]	110,364

[1] Census reports 95,318 tons of gypsum products.

Slate.—Roofing slate has been found in many localities in the state and quarries have been opened in Orange, Dutchess, Columbia, Rensselaer, and Washington counties. The only productive slate quarries, however, are in a narrow belt lying entirely within Washington county. The stone varies in color from red and purple to green and is of excellent quality.[2]

The 11 quarries productive in 1902, all in Washington county, had an output valued at $126,718—an increase of $25,758 over 1901.

Garnet.—This mineral is found in Warren county, on the borders of the Adirondack region, and in Essex and St. Lawrence counties. The entire deposits in Warren county appear to be of the common variety, almandine. It occurs in a formation of crystalline limestone and in gneissic rocks which adjoin or are intercalated with the crystalline limestone. Commercially this mineral is classified as massive garnet, shell garnet—the most valuable for industrial purposes on account of its purity—and pocket garnet.[3] The garnet is used almost exclusively in the manufacture of sandpaper, or garnet paper, which is used for abrasive purposes by manufacturers of boots and shoes and by wood manufacturers.

In 1902 garnet was mined commercially in Essex, Warren, and St. Lawrence counties, but the work done in St. Lawrence county was more or less experimental. The total production for the state in 1902 was 2,760 tons, valued at $97,600. As the total output of garnet in the United States for 1902 was 3,926 tons, valued at $132,820, New York state produced 73.5 per cent in value of the entire product shown for the country.

Graphite.—Deposits of graphite are known to exist throughout the Adirondack region, but the mining of crystalline graphite in this portion of the state has been practically confined to a comparatively small section in the southeast portion of Essex county and in the northeast part of Warren county.[4] There are also occurrences of graphite in Dutchess county and several tons have been obtained from them.[5]

The material in the mines near Ticonderoga, in Essex county, is in a vein of the purest foliated graphite, several inches in width. The folia often have a radiated arrangement and are of considerable size. The gangue is calcareous spar, which sometimes exhibits large and perfect cleavages. At Johnsburg, in Warren county, the mineral occurs in irregular shaped masses, weighing from 1 to 20 pounds, in a vein of quartz.[5]

Early in the last century, after the accidental discovery in 1815 of a deposit at Ticonderoga, in Essex county, graphite mining was carried on, in a primitive manner, by the farmers owning the land, and the material, ground with considerable magnetic iron ore, was used for stove blacking.[4]

In 1830 the invention of the lead pencil aroused increased interest in the Essex county mines. New openings were made in the mountain side and pencil leads were made from the crude graphite in the vicinity of the mines. In 1863 the American Graphite Company acquired these properties, an extensive mill was erected, and the industry increased so rapidly that the annual production reached 500 tons in 1869. Subsequently the same company acquired the Warren county properties.[4]

In 1902 the three productive mines of the state,

[5] Mineralogy of New York, pages 97 and 98.

located in Essex and Warren counties, produced 1,375 tons of crystalline graphite, valued at $77,437. As the total quantity of this mineral mined in the United States in 1902 was 1,983 short tons, the contribution of New York state was 69.3 per cent of the whole.

Corundum and emery.—The emery mines of the state are located in Westchester county, near Peekskill. In most cases they are abandoned iron mines, emery not having been recognized when iron ore was being mined in this region. As the emery outcrops on the hillsides, the mines are usually shallow openings or quarries.[1]

The output of the 3 mines productive in 1902 was 2,886 tons, or 67.9 per cent of the production of corundum and emery for the United States. The value of the New York emery was $44,625.

Buhrstones and millstones.—In the United States the millstone varies from a sandstone to a quartz conglomerate. The rock from which it is made occurs along the eastern slopes of the Appalachian mountains from New York to North Carolina and is known by various names. In New York state it is called "Esopus stone" and is found in Ulster county, in the Oneida conglomerate. Millstones are now used extensively for grinding the coarser cereals, mineral paint ores, fertilizers, cement rock, barytes, and other minerals. Before the introduction of the roller process in milling, millstones were used principally in grinding wheat.

The 22 operators of the state reported for 1902 a production of 5,158 stones, valued at $39,570. All the quarries from which the rock was taken were in Ulster county. As the value of the buhrstones and millstones made in the United States in 1902 was $59,808, New York state alone furnished 66.2 per cent of this amount.

All other minerals.—Deposits of clay occur in nearly every county in the state, but the most important are those of the Hudson valley. This region is probably the most active brickmaking region in the world. In 1902 its operators produced 782,932,000 common brick, or 73.7 per cent of the total output of common brick reported for the state. The production was exceeded by only two states. New York ranked fifth among the states in 1902 in the value of its products of clay, which amounted to $8,414,113. The value of the clay mined and sold by the 7 operators in 1902 was $14,535.[2]

The crystalline quartz mined in Dutchess county in 1902 was used as a wood filler. No statistics can be shown for the single operator of the state without disclosing individual operations. The single productive feldspar mine of the state in 1902 was near Bedford, in Westchester county. The two productive flint mines in the state in 1902 were both in Westchester county. The deposit of infusorial earth of White Lake at Wilmurt, in Herkimer county, is dug from the bottom of the lake, which covers about 4 acres, and has a thickness of from 2 to 30 feet, being covered by about 4 feet of water.[3] As early as 1740 lead ore is said to have been mined in Dutchess county, and in both Columbia and St. Lawrence counties it was mined early in the last century. The presence of both lead and zinc was known in many other localities throughout the state, and much money was expended in the exploitation of this industry.[4] Only one mine, in St. Lawrence county, was productive in 1902. Under the classification "mineral pigments, crude," are the statistics for the production of ores used in the manufacture of mineral paints. Such ores were produced during 1902 in Cattaraugus, Rensselaer, and Washington counties, but the entire output of the 5 mines was only 1,261 tons, valued at $4,251. The single productive pyrite mine in the state in 1902 was located in St. Lawrence county.

NORTH CAROLINA.

Table 1 is a summary of the statistics for the productive mines and quarries of the state of North Carolina for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Siliceous crystalline rocks.	Talc and soapstone.	Gold and silver.	Mica.	Monazite.	Barytes.	All other minerals.[1]
Number of mines or quarries	126	30	6	15	28	23	5	19
Number of operators	137	27	6	15	26	22	5	36
Salaried officials, clerks, etc.:								
Number	120	31	12	21	4	3	13	36
Salaries	$84,244	$23,578	$7,710	$18,267	$1,411	$2,100	$5,401	$25,757
Wage-earners:								
Average number	1,556	615	62	203	50	88	34	504
Wages	$517,765	$222,868	$21,416	$66,822	$15,160	$25,318	$9,914	$156,267
Contract work	$9,000						$1,000	$8,000
Miscellaneous expenses	$76,842	$16,463	$27,981	$10,238	$2,952	$2,083	$5,886	$11,239
Cost of supplies and materials	$118,782	$42,884	$12,447	$26,490	$3,121	$256	$2,740	$30,844
Value of products	$927,376	$338,750	$88,962	$71,287	$71,148	$64,160	$44,130	$248,939

[1] Includes operators as follows: Buhrstones and millstones (operator reported under siliceous crystalline rocks); clay, 3; coal, bituminous, 1; copper ore, 2; garnet, 1; graphite, 2; iron ore, 3; limestones and dolomites, 4; precious stones, 18 (1 mine); sandstones and quartzites, 2.

The state ranked forty-second in 1902 in the value of products of mines and quarries, with a total of $927,376. This small product (less than one-eighth of 1 per cent of the total for the United States) should not be taken, however, as a measure of the state's relative importance in quantity and diversity of mineral resources. The minerals contributing to this total and arranged in the order of values were siliceous crystalline rocks, talc and soapstone, clay, gold and silver, mica, monazite, iron ore, barytes, bituminous coal, copper ore, limestones and dolomites, garnet, precious stones, sandstones and quartzites, buhrstones and millstones, and graphite.

It will be noted that the production of gold and silver in 1902 was exceeded in value by that of siliceous crystalline rocks and talc and soapstone, and almost equaled by that of mica and monazite. Also that copper and iron ore occupy relatively minor positions, while no yield of zinc ore was reported. These facts suggest the changing character of the state's mineral product and the somewhat checkered and interesting nature of its mining history.

A number of minerals occurring in the state in commercial quantities were not produced in 1902. Asbestos has been found on Tryon mountain, Polk county, about 1½ miles west of Skyuka. It is of the amphibole variety and occurs in what is apparently a series of pockets, which have been traced across the country for nearly a mile. One pocket that was opened measured nearly 100 feet in width. It is of fair quality, and large masses have been taken out in which the fiber was from 10 to 15 inches long. The chromite mines of Yancey county give indications of containing large deposits, and there is a promising deposit on Dark Ridge creek, in Jackson county. Another property recently developed is on Big Ivy creek, Buncombe county, 16 miles northwest from Asheville. Several veins of the black oxide of manganese of considerable extent have been found. Oil shale exists in great thickness in connection with the coal beds and yields a large percentage of oil.[1] Phosphatic deposits were first systematically examined and studied in 1884 by the state survey. They were found to be of two classes. The first class consists of amorphous nodules, occurring in small quantities in Sampson, Pender, Onslow, Duplin, Columbus, and New Hanover counties. These are of little value commercially. The other class is that of the phosphatic conglomerates found in beds of from 1 to 6 feet thick, and located principally in New Hanover and Pender counties. While the percentage of phosphate of lime in these conglomerates does not average over 10 to 20 per cent, they have been ground by several companies for local consumption.[2] Grains of platinum have been discovered among the sands of gold washings in Rutherford and Burke counties, and

[1] Handbook of North Carolina, by L. L. Polk, page 129.
[2] Eleventh Census, Report on Mineral Industries, page 690.

also near Burnsville, in Yancey county.[1] Nickel minerals in small quantities are associated with many of the basic manganesium rocks. Genthite and garnierite have been found, but thus far they have not been discovered in sufficient quantity to make them a commercial source of nickel. A deposit of nickel ore averaging 1.5 per cent of the metal is located near Morganton, Burke county. Pyrite, which is one of the most common minerals in the state, is found especially in the counties of Catawba, Gaston, Chatham, Union, and Mecklenburg.[2]

Other minerals which have been found are: Epidote, ilmenite, manganese ore, manganiferous iron ore, marble, rutilated quartz, rutile, sperrylite, tungsten, uranium, and vanadium.

In addition to the productive mines and quarries of the state, extensive development work was carried on during 1902 on 29 nonproductive mines and quarries, the total outlay in this line amounting to $200,915. Most of this expenditure was applied to the development of gold and silver deposits, phosphate rock and clay sharing the remainder in the order named.

The relative importance of those manufacturing industries which are closely allied to or based upon the mining industry, using as their raw material the product of the mine or quarry, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$94,919,663
Based upon products of mines or quarries:		
Chemicals and allied products	$1,501,024	
Clay, glass, and stone products	1,162,061	
Iron and steel, and their products	1,611,504	
Metals and metal products, other than iron and steel	243,836	
Miscellaneous industries	1,261,978	
		5,780,403
All other		89,139,260

As shown by Table 2, the total value of the products of the manufacturing industries based primarily on mines and quarries was $5,780,403, or 6.1 per cent of the product of all manufacturing industries in the state in 1900.

During the same year there were employed in all branches of manufacture in the state 70,570 wage-earners, who were paid $13,868,430 in wages. In 1902 there were employed in the mines and quarries of the state 1,556 wage-earners, who received $517,765 in wages. On the basis of these figures it is seen that 97.8 per cent of the wage-earners of the combined industries, receiving 96.4 per cent of the wages, were employed in manufacturing, while 2.2 per cent of the wage-earners, receiving 3.6 per cent of the wages, were employed in mining.

[1] Estimates of the Director of the Mint for the refined product; silver at coining value. The values given in Table 1 are the values at the mine.
[2] Not reported separately.
[3] No production.
[4] Includes production from South Carolina.
[5] Silver at commercial value.
[6] Census figures, except for gold and silver.

Siliceous crystalline rocks.—Granite and gneiss are among the commonest rocks of the state, being found in all sections except the coastward region. The principal producing counties where good grades of building granites are found are Gaston, Iredell, Rowan, Surry, and Wilkes.[3]

Talc and soapstone.—Talc is a very common mineral in North Carolina, both in the form of the impure greenish massive or slaty rock (potstone), used for monuments and for chimney and furnace hearths and linings, and in the form of a pure massive white steatite. The product for the year 1902 was reported from Cherokee, Moore, and Swain counties, and constituted 7.8 per cent of the total product of the United States. The most extensive beds of this mineral are found in Cherokee and Macon counties in immediate association with the marble range along the Nantahala, Valley, and Nottely rivers.[4]

Clay.—Many varieties of clay of varying value are found at many points in the state, especially in Guilford, Chatham, Wake, Harnett, Robeson, Lenoir, and Jackson counties.[5] In Jackson county extensive beds of kaolin of high grade have been found, and the total clay product of the state for 1902 came from this county.

Gold and silver.—Gold was the principal product of the mines of this state for nearly three-fourths of a century. It is widely distributed, but its principal field is the eastern slope of the Blue Ridge. Silver, on the whole, is a rare mineral in North Carolina. It has been obtained in considerable quantities at Silver Hill, in

[3] Geology of North Carolina, Vol. I, page 271 ff.
[4] Ibid., page 298.
[5] Ibid., page 296.

Davidson county. Other counties in which silver has been found and in some instances mined with indifferent success are Burke, Caldwell, Wilkes, Gaston, Cabarrus, Union, Montgomery, McDowell, Madison, Johnston, Cherokee, and Surry.[1]

From the earliest days of placer gold mining in 1799 on the tributaries of the Pedee down to the decade immediately preceding the Civil War, North Carolina ranked as a mining state of the first importance. The bulk of the mining done in the state during this period was gold mining, and from 1804 to 1827 all the gold produced in the United States, amounting to $110,000, came from the mines of this state.[2] That part of the product of the gold mines of the state which was deposited in the United States Mint and its branches between 1804 and 1866 amounted to nearly $10,000,000.

After the working out of the principal placer deposits, and when the progress in quartz mining had reached the point where, owing to the fineness of the gold and the increasingly refractory character of the ores as the water level was reached, further profitable prosecution of mining with the crude machinery then in use had become a problem of doubtful solution, a decline took place in mining activity. This decline was greatly accentuated by the discovery in California in 1848 of rich placer deposits and by the beginning in 1851 of quartz mining in the same state, where high-grade, free-milling ores had been found in great abundance. Finally, the advent of the Civil War and the discontinuance of the branches of the United States Mint at Charlotte, N. C., and Dahlonega, Ga., brought to a practical close this long and interesting period of mining activity in the state's history.

Since 1866 mining for gold has been carried on in the state in a somewhat desultory way, and in later years other minerals and other sections of the state have claimed attention. The mineral wealth of the state is by no means confined to the eastern slope of the Blue Ridge—the principal gold belt. West of that range, between Smoky mountains and the Blue Ridge, and from the upper water of the French Broad river westward, there is a rich mining field.

Mica.—Mica is found in a half dozen or more counties in the state, most of which lie west of the Blue Ridge. The most noted localities are in Mitchell and Yancey counties on the waters of the Nolichucky between the Black mountain and the Roan. In this basin are a great many enormous ledges of granite from which the marketable mica is obtained.[3]

Modern mica mining in the state dates from 1870, since which time North Carolina has produced a very important percentage of the total yield of this mineral in the United States. In 1870 the entire reported product of the country was from this state. In 1880 it was 48.3 per cent; in 1890, 13.3 per cent; and in 1902, 59.9 per cent of the total.

There is one point of unusual interest connected with the history of mica mining in this state. The industry is not really a new one, but has only been revived. The present workings are continually cutting into ancient shafts and tunnels, and hundreds of spurs and ridges of the mountains, especially all over Mitchell county, are found to be honeycombed with extensive ancient workings of which no one knows the date or history. In one locality open pits 40 to 50 feet wide by 75 to 100 feet long, filled up to 15 or 20 feet of depth, are disposed along the sloping crest of a long terminal ridge or spur of a neighboring mountain. The excavated earth is piled in huge heaps about the margins of the pits and the whole overgrown with the heaviest forest trees—oak and chestnut—some of them 3 feet and more in diameter, and some of the largest, belonging to a former generation of forest growth, fallen and decayed.[3] It would thus appear that not less than three hundred years have passed since these pioneer toilers wrote in the unmistakable language of pits and tunnels the first chapter of the history of mining in the state. These old workings were at one time thought to be abandoned Spanish silver mines. There is no appearance, however, of a silver vein and no explanation of the object of these extensive works other than that they were for the purpose of obtaining the large plates of mica or crystals of cyanite, both of which abound in the coarse granite rock. It is known that mica was of common occurrence in the tumuli of the Mound Builders, among the utensils and ornaments which such primitive people were in the habit of burying with their dead. Many cut forms similar to those found in the mounds have been discovered among the rubbish and refuse heaps about and in these old pits. These facts reveal, therefore, the purpose and probable date of these ancient workings and show them to have been contemporary with the extensive copper mining operations of Lake Superior.[4]

Monazite.—The total product of monazite mining in the United States reported in 1902 came from the state of North Carolina. While the existence of monazite in commercial quantities in this state was first established in 1879, by Mr. W. E. Hidden, of New York, who, in the interest of Thomas A. Edison, the inventor, inspected the gold placers on a hunt for platinum, the first recorded product of monazite mining in the state was in 1887, and came from the Brindleton district, in Burke county.[5]

Iron ore.—The first recorded discovery of iron ore in North America occurred in the year 1585, in North

Carolina. It was made by an expedition fitted out by Sir Walter Raleigh, and commanded by Ralph Lane, and which attempted to plant an English colony on Roanoke Island. The ore was found near the coast, and although the importance of the discovery was fully realized, no attempt was made to utilize it, as the colonists were then on a search for gold. It was many years after that a permanent settlement was made, and the industry of iron mining and manufacture was well under way in many other colonies before its beginning here.[1] Iron ores of high grade and in large quantities have been found in many sections of the state, and at different periods during the last hundred and twenty-five years the production of iron in the state was an industry of relatively marked importance. The ranges of iron ore deposits are widely distributed, but in the main fall within the following counties: Chatham, Orange, Guilford, Gaston, Lincoln, Catawba, Yadkin, Surry, Stokes, Mitchell, Ashe, Madison, Cherokee, and Johnston.[2] The product of the state is still small. That reported for 1902 came from Johnston, Madison, and Mitchell counties.

Barytes.—The commercial production of barytes in North Carolina, first noted at the census of 1889, is confined chiefly to Madison county, though deposits have also been found in Gaston, Orange, Cabarrus, and Union counties.[3] For the year 1902 the production of barytes was $44,130, or 21.7 per cent of the total product of the United States.

All other minerals.—Deposits of bituminous coal exist in the state in Stokes and Rockingham counties, in the valley of the Deep river. Coal has also been found in Chatham and Moore counties.[4] No statistics can be shown without disclosing individual operations.

Copper ore is found in many places in the state, the principal variety being chalcopyrite, or copper pyrites. Before the Civil War the industry of copper mining had made considerable headway. Many of the gold veins are associated with pyritic ores, practically all the old copper mines of the central part of the state having been worked first for gold. The general character of these mines was that at about water level the so-called "brown gold ores" were replaced by quartz richly charged with iron pyrites more or less mixed with copper pyrites, the latter increasing as the mine deepens, and in many places becoming the only or the predominating ores, and forming a regular copper vein. Perhaps the most valuable deposits of copper in the state are in Ashe, Alleghany, and Watauga counties; the most remarkable vein in this range is at Ore Knob, in the southeast corner of Ashe county, near the top of the Blue Ridge.[5]

Abrasive garnet is widely distributed through the state, and is a regular constituent of many of the mica and hornblende slates. Large crystals of a brownish red color are frequently met with in the mica mines of Mitchell and Yancey counties. The product of the North Carolina garnet mines has obtained the highest price in the market, $60 per ton. The total product of the state for 1902 was from Jackson county.

Graphite occurs in many localities in the state. The largest beds are in Wake county. Others occur in Lincoln, Cleveland, Catawba, Alexander, Stokes, Wilkes, Person, and Yancey counties.[6]

Limestones though not abundant are found in more than twenty counties, and distributed throughout the state. Those in the eastern part are a shell conglomerate, valuable both for building purposes and for the manufacture of lime. Those of the middle and western section are frequently crystalline, and in several counties, especially in Cherokee and Macon, constitute a very good marble.

Precious stones have been picked up at many places in the central and western part of the state. Among these have been a half dozen or more diamonds. The first one was found in 1843 by Dr. M. F. Stephenson, of Gainesville, Ga., at the ford of Brindleton creek, in Burke county, and was worth about $100.[7] Garnet crystals of great beauty and perfection and of various colors are found in Burke, Caldwell, and Catawba counties.[8] A peculiar green garnet has been found in the Covee valley, for which the name rhodolite has been generally adopted. Many emerald matrix specimens have been found at Crab Tree mountain in Mitchell county. Mining for amethyst has met with considerable success at Tesnaty, on the creek of that name, in Smith Bridge township, Mitchell county, where a large vein occurs in an altered pegmatite. Crystals are found from one-half to 3 inches in length, and in color they are light and dark, the dark spots often being of the deepest, richest purple. No finer amethysts have been found in the United States. Several thousand dollars worth of stones were sold from the first development work. A very interesting new form of moonstone has been found near Bakersville. The well-known occurrence of pink and red ruby corundum in a green amphibole

(smaragdite) at Buck creek, Clay county, has been utilized as a new semiprecious stone. Pieces are selected in which the bright spots of red or pink ruby are inclosed in the bright green matrix. The stone is being introduced under the name of ruby matrix.

Sandstone of a superior quality has long been quarried in the state. It is found in two narrow zones, one lying along the valley of the Dan river, near and almost parallel to the northern boundary of the state, and the other lying in a northeast and southwest direction, nearly across the eastern side of the middle division of the state.[1] In many places it is of such character as to be well adapted to the purposes of millstones. Conglomerates, which are associated with the sandstone, have been made into excellent millstones, occasionally of such quality as to be almost equal to the French buhrstone. The rocks have been quarried for millstones in Anson, Moore, Madison, Person, Montgomery, and Rowan counties.[2] The total product of the state in 1902 was from Rowan county.

NORTH DAKOTA.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of North Dakota for 1902.

TABLE 1.—*Summary: 1902.*

	All minerals.[1]
Number of mines or quarries	48
Number of operators	48
Salaried officials, clerks, etc.:	
Number	52
Salaries	$43,980
Wage-earners:	
Average number	298
Wages	$196,534
Contract work	$2,795
Miscellaneous expenses	$23,012
Cost of supplies and materials	$88,867
Value of product	$334,967

[1] Includes operators as follows: Cement, 1; and coal, bituminous, 47.

The lignite coal area of this state is of very great extent, equal to at least half the area of Ohio.[1] Although known for some time the coal fields are of only recent development. Some cement of good quality is manufactured.

There is also every reason to believe that large sandstone quarries will in time be developed, since there are a number of suitable locations only awaiting a sufficient demand to justify extensive development. Granite and gneiss are also found throughout the eastern half of the state, except in the Red river valley, but are not quarried in commercial quantities. The clay fields in the state are wholly undeveloped.[2]

The value of the products of the manufacturing industries of North Dakota, based primarily upon minerals mined and quarried as well as the value of all manufactured products of the state as reported at the Twelfth Census are presented in the following table:

[1] Geological Survey of North Dakota, Second Biennial Report, 1902, page 35.

[2] Ibid., pages 28 to 32.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$9,183,114
Based upon products of mines or quarries:		
Clay, glass, and stone products	$198,224	
Iron and steel and their products	103,511	
Metals and metal products, other than iron and steel	167,864	
Miscellaneous industries	874,560	
		1,344,159
All other		7,838,955

Table 2 shows that the value of products of manufactures of North Dakota in 1900, based primarily upon minerals mined and quarried, was $1,344,159, or 14.6 per cent of the total. The value of the output of the mines and quarries of the state in 1902 was $334,967, or 3.5 per cent of the combined value of products of manufacturing and mining in North Dakota.

The average number of wage-earners engaged in manufactures in North Dakota as reported at the Twelfth Census was 2,398, and the wages paid amounted to $1,222,472. The average number of wage-earners engaged in mining and quarrying in the state in 1902 was 298, and the wages paid were $196,534. The total number of wage-earners, therefore, employed in mining and manufacturing industries was 2,696, and their wages amounted to $1,419,006. On the basis of these figures, those engaged in manufactures constitute 88.9 per cent of the total number of wage-earners, while their wages amount to 86.1 per cent of the total paid. The wage-earners employed in mining industries constitute 11.1 per cent of the total number employed, and they received 13.8 per cent of the wages paid.

Coal.—Lignite coal in North Dakota underlies an area of 28,620 square miles. This area is a part of the

so-called Rocky mountain coal field, which also includes the coal areas of Montana, Wyoming, Utah, Colorado, New Mexico, Idaho, and Nevada.[1] The earliest production of coal worthy of statistical notice was produced in 1884.[1] The North Dakota variety does not stand transportation well, and consequently can not compete with bituminous coal, except when the latter is high priced. To be sold at a profit, therefore, North Dakota coal must at present find a comparatively local market.[1]

In 1902 the mines of the 47 operators reporting were located in Burleigh, McLean, Morton, Stark, and Ward counties. The total output was 226,511 short tons. Ward county produced 93,786 tons of this amount.

The following figures taken from the reports of the United States Geological Survey show the quantity and value of the coal mined in the state since 1884:

[1]United States Geological Survey, "Mineral Resources of the United States," 1902, page 402.

TABLE 3.—*Annual production of coal, bituminous: 1884 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	Value.	YEAR.	Short tons.	Value.
1884	35,000	(1)	1894	42,015	$47,049
1885	25,000	$91,000	1895	38,997	41,646
1886	25,955	41,277	1896	78,050	84,908
1887	21,470	32,205	1897	77,246	83,803

1893	49,630	56,250			

[1] Not reported.

Cement.—No data relative to the single cement plant in the state can be shown without disclosing individual operations. However, it may be said that the plant has been erected about five years and has been a successful though not a very large producer. The plant is located at Pembina, on the Tongue river.[2]

[2] United States Geological Survey, "Mineral Resources of the United States," 1902, page 802.

OHIO.

Table 1 is a summary of statistics for the productive mines, quarries, and wells in the state of Ohio for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Petroleum.	Limestones and dolomites.	Natural gas.	Sandstones and quartzites.[1]	Cement.	Grindstones and pulpstones.	All other minerals.[2]

Contract work	$2,701,557	$46,818	$2,212,923	$7,276	$433,026				$1,514
Miscellaneous expenses	$7,711,026	$1,619,451	$4,896,861	$139,648	$491,223	$437,827	$71,829	$9,982	$44,205
Cost of supplies and materials	$10,126,452	$2,082,788	$5,504,792	$560,462	$1,139,201	$526,521	$231,322	$19,777	$61,589
Value of product	$57,186,922	$26,953,789	$20,757,359	$3,204,998	$2,355,458	$2,078,754	$714,551	$560,412	$561,601

[1] Includes operating expenses for the production of grindstones and pulpstones, valued at $399,726.
[2] Includes operators as follows: Clay, 31; gypsum (operator reported in Michigan); iron ore, 9; oilstones, whetstones, and scythestones, 1; phosphate rock, 1; silica sand, 7; sulphur and pyrite, 3.

The coal fields of Ohio are extensive and have been yielding over 10,000,000 tons annually since 1889. The petroleum and natural-gas output is very large, a number of the most productive wells in the country being found in this state. Some of Ohio's building stones are among the finest in the United States, and find a ready market. Practically the entire output of grindstones and all the pulpstones produced in this country come from this state. To supply its extensive iron and steel industries Ohio depends on other states for the necessary iron ore, as its own deposits are not rich either in quantity or quality. Ohio is one of the leading states in the manufacture of Portland cement, and has long been a producer of natural rock cement. Sandstone abounds and when crushed and screened is used in glassmaking and for other purposes. Large and valuable deposits of clay aid in giving the state its leading position in the clay working industries.

In addition to the minerals referred to in Table 1, strontium ore is found at Put in Bay, Ottawa county, but none has been produced in commercial quantities since 1897.

The operators reporting active mines and wells, but no production, gave employment to 204 wage-earners and paid $122,722 in wages during 1902. The cost of supplies and materials amounted to $27,912, and of contract work to $14,174.

The relative importance of manufacturing industries closely allied to or based upon the mining industry, using as their raw material the product of the mine or quarry, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$832,438,113
Based upon products of mines or quarries:		
Chemicals and allied products	$18,795,296	
Clay, glass, and stone products	29,630,884	
Iron and steel and their products	255,219,520	
Metals and metal products, other than iron and steel	16,451,954	
Miscellaneous industries	27,722,917	
		347,820,571
All other		484,617,542

From the foregoing table it will be seen that the value of the products of manufactures based primarily upon minerals mined and quarried was $347,820,571, or 41.8 per cent of the total. The value of the output of the mines, quarries, and wells of Ohio for 1902 was $57,186,922, or 6.9 per cent of the total value of all manufacturing and mining products for the state.

The Twelfth Census reported the average number of wage-earners engaged in manufactures in Ohio as 345,869 and the wages paid as $153,955,330. The average number of wage-earners engaged in mining in 1902

was 37,173, and the wages paid were $23,222,680. The manufacturing and mining industries combined gave employment to 383,042 wage-earners and paid $177,178,010 in wages. Manufactures employed 90.2 per cent of the wage-earners and paid 87 per cent of the wages, while mining employed 9.8 per cent of the wage-earners and paid 13 per cent of the total wages.

The following table, compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals of this state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Petroleum.	Limestones and dolomites.	Natural gas.	Sandstones and quartzites.	Cement.
1890	$10,783,171	$5,644,195	$1,514,934	$4,684,300	$3,046,656	$49,000
1891	12,106,115	5,576,705	1,250,000	3,076,325	3,200,000	82,000
1892	12,722,745	6,239,039	2,025,000	2,136,000	3,300,000	108,500

1902[1]	26,953,789	20,757,359	3,204,998	2,355,458	2,078,754	714,551

[1] Census figures.

Coal.—The coal fields of Ohio underlie between 10,000 and 12,000 square miles of the state area, and are located in some thirty counties in the eastern and southeastern portion of the state. They belong to the northern Appalachian system, which also includes the coal areas contained in western Pennsylvania, Maryland, Virginia, West Virginia, and eastern Kentucky. The coals are all of the bituminous variety and are known in general terms as block, gas, cannel coal, etc., and by special names indicating the producing localities. At what period the deposits first became known is uncertain, but they were known to exist certainly as early as 1770.[1] Although some coal was undoubtedly produced prior to 1828,[2] when the first recorded shipment was made, the first production recorded was in 1838. The history of the output was not kept with any accuracy before 1872.

Of the 29 coal producing counties in Ohio in 1902, 9 had a production of 1,000,000 tons or over, and of the 648 mines 2 had an output of 1,000,000 tons or over, and 51 an output of 100,000 tons or over. The largest coal producing counties were Athens, Belmont, Guernsey, Hocking, Jackson, Jefferson, Perry, Stark, and Tuscarawas. Ohio ranked second in quantity of product among the coal states until 1883, when Illinois outranked it; in 1896 West Virginia ranked third, Ohio taking fourth place. This place it still held in 1902, although in value of coal produced it ranked third.

The following table shows the annual production of coal in Ohio from 1838 to 1902. The figures for many of the years prior to 1872 are estimates.

TABLE 4.—*Annual production of coal, bituminous: 1838 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.
1838	119,952	1871	4,000,000
1839	125,000	1872	5,315,294

1870	2,830,559		

Petroleum.—As early as 1814 petroleum was obtained in brine wells, but it was not until after Drake's discovery on Oil creek, Pa., in 1859, that the oil region in the southeastern part of Ohio began to attract attention.[3] The Trenton rock, or Lima district, in the northwestern part of the state, did not receive any serious consideration until 1885, when the great Cincinnati arch began to be looked upon as a probable factor in the crude petroleum field.[4] The Trenton rock petroleum comes from a limestone instead of a sandstone formation, is dark in color, and contains a considerable quantity of sulphureted hydrogen, making it rather refractory for refining purposes. The Lima district, extending through Wood, Hancock, Allen, Sandusky, Auglaize, Mercer, Van Wert, Lucas, Wyandot, and Ottawa counties, has been one of the largest producers in the United States, and in 1902 its production was about 75 per cent of the petroleum produced in Ohio.

Since 1895 Ohio has ranked first among the petroleum producing states. In 1902 its 42,483 wells had an output of 21,014,231 barrels, or nearly 24 per cent of the entire production of the United States for that year. While Ohio's petroleum output for 1902 was less than that for 1901, the product sold at an increase in price averaging 4 cents per barrel.

1886	1,782,970	1901	21,648,083
1887	5,022,632	1902	21,014,231

Limestones and dolomites.—These stones are mentioned in the Second Annual Report of the Geological Survey of Ohio as having been used as early as 1838 for building, burning into lime, macadamizing roads, and even for ornamental purposes. They are almost uniformly of a dull color, and though in many cases durable and strong, are entirely unfit for any sort of fine building or ornamental work. They are, therefore, used chiefly for the rough work of foundations, street paving, and flagging, and to a very large extent for making quicklime.[1]

Ohio in 1902 ranked third in value of product in the list of limestone producing states, being exceeded by Pennsylvania and Illinois.

Natural gas.—There are three natural gas fields in Ohio. The first known field was along the eastern margin of the state, where occur the sands of the Lower Coal Measures, the Waverly Series, and the Ohio shales. The second field, the last to be developed, is in the central portion of the state and receives its natural gas from the Clinton limestone of the Upper Silurian series. The third field is found in the northwestern portion of the state and obtains its natural gas exclusively from the upper portion of the Trenton limestone of the Lower Silurian series. Natural gas was first used in Ohio in 1866 in the manufacture of lampblack at Gambier, Coshocton county; in 1874 it was used at East Liverpool, in the household, for heat and light. The great Trenton rock gas field was first opened at Findlay in November, 1884, and the Lancaster gas field was developed by a well drilled near that city in 1887.[2] The gas produced from the eastern portion of the state was not developed in sufficient quantities to warrant the piping of it to far distant localities, but it has been an important factor in supplying many nearby towns and industries.

The value of the natural gas produced in Ohio in 1902 was $2,355,458, which is an increase of $208,243 over 1901. The greatest production was in 1889, after the great Findlay gas field had been first opened; the smallest production was in 1897, just before the Lancaster and Sugar Grove pools were developed. Of the 1,352 wells in operation during 1902, the 637 wells located in the counties of Fairfield, Franklin, Hancock, Licking, Knox, Belmont, Guernsey, Noble, and Mercer produced natural gas valued at $2,107,731. The remaining 715 wells were located in the following counties: Allen, Ashtabula, Auglaize, Columbiana, Cuyahoga, Darke, Hardin, Harrison, Holmes, Lake, Logan, Lorain, Lucas, Monroe, Morgan, Ottawa, Sandusky, Stark, Van Wert, Washington, and Wood.

Sandstones and quartzites.—Quarries of excellent sandstone abound in Ohio, of which the so-called Waverly group are the most important for building purposes.[3] The greatest sandstone deposits, known geologically as the Berea grit, are located in Cuyahoga and Lorain counties. The stone, of a very light buff, gray, or blue-gray color, is famous for its evenness of color and purity of texture, and for building purposes finds a ready market throughout the United States. The value of the sandstone quarried in these two counties in 1902 for building purposes amounted to $828,284.

The value of the sandstones and quartzites production of Ohio for 1902, $2,078,754, is exceeded only by that of Pennsylvania. These figures do not include the value of stone quarried for grindstones and pulpstones. The 115 quarries operated during 1902 were located in the following counties, arranged according to the value of the production: Cuyahoga, Lorain, Scioto, Fairfield, Summit, Erie, Richland, Morrow, Belmont, Carroll, Huron, Muskingum, Mahoning, Trumbull, Crawford, Holmes, Harrison, Jefferson, Stark, Morgan, Tuscarawas, Washington, Meigs, Pike, Columbiana, Ashtabula, Guernsey, Licking, Delaware, Miami, Pickaway, Highland, and Perry.

Cement.—Among the first cement plants to be established was a small one at Sandusky, about 1845. In 1846 a plant was established at Defiance, and in 1858 at Barnesville. The first Portland cement plant was established in 1889.[4] In 1902 Ohio ranked seventh among the states manufacturing this material. While the growth of this industry in Ohio has been steady, it has not been as marked as in some other states. In 1890 the production amounted to only 57,000 barrels while in 1902 it amounted to 563,113 barrels. But one company now produces natural rock cement.

Grindstones and pulpstones.—Four-fifths of all the grindstones produced in the United States are quarried in Ohio, the sandstone known as the Berea grit being the greatest source of supply. The 7 quarries operating

[3] Stones for Building and Decoration, page 154.

[4] United States Geological Survey, "Mineral Resources of the United States," 1902, page 803.

in 1902 were located in Cuyahoga, Stark, Jefferson, Athens, and Washington counties. The value of the total output in Ohio was $560,412, while that of the United States was $667,431.

The following table shows the value of the annual production of grindstones, 1899 to 1902, it being impossible to segregate the production from the total for the United States previous to 1899:

TABLE 6.—*Value of annual production of grindstones: 1899 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Value.	YEAR.	Value.
1899	$480,963	1901	$548,844
1900	542,721	1902	560,412

All other minerals.—The value of raw clay produced by the 31 operators in 1902 was $101,305.

The single gypsum plant in the state is near Gypsum, in Ottawa county. The product is converted principally into wall plaster.

The first blast furnace in Ohio was completed in 1804, in Mahoning county,[1] and it is probable that iron ore was first mined in this state about that time. The Hanging Rock district, in Lawrence county, along the Ohio river, was once quite a source of supply, but during late years the quantity of iron ore mined in Ohio has steadily decreased, owing probably to the inferiority of the ore. In 1889 the production of iron ore in Ohio amounted to 254,294 long tons, while in 1902 it was only 22,657 long tons.

The silica sand production for 1902 was valued at $152,274. A little less than a quarter of this crushed sandstone is used in the manufacture of glass.

At a number of the quarries in the Berea sandstone district a grade of stone is found suitable for making whetstones. The well-known Deerlick oilstone is made at Chagrin Falls, Cuyahoga county. The value of the production of whetstones and oilstones in Ohio can not be shown separately without disclosing the operations of an individual establishment.

The pyrite produced by three operators in Tuscarawas county is a by-product of coal. The phosphate rock produced is found in Mahoning county.

OKLAHOMA.

Table 1 is a summary of the statistics for the productive quarries and wells in the territory of Oklahoma for 1902:

TABLE 1.—*Summary: 1902.*

	Total.	Limestones and dolomites.	All other minerals.[1]
Number of quarries and wells	21	12	9
Number of operators	17	12	5
Salaried officials, clerks, etc.:			
Number	18	4	14
Salaries	$12,223	$3,035	$9,188
Wage-earners:			
Average number	128	46	82
Wages	$64,545	$22,277	$42,268
Miscellaneous expenses	$15,830	$840	$14,990
Cost of supplies and materials	$31,934	$6,737	$25,197
Value of product	$186,706	$50,541	$136,165

[1] Includes operators as follows: Gypsum, 3 (5 quarries); petroleum, 1 (3 wells); sandstones and quartzites, 1.

From the above table it appears that mining in Oklahoma during 1902 was confined to the quarrying of limestone, gypsum, sandstone, and the operation of three petroleum wells. Gypsum is by far the most important product of mineral industry in the territory.

Many stories have been circulated from time to time regarding old Spanish mines existing in Oklahoma,[1] but they have little foundation. It is claimed, however, that dates cut in the rocks in the Wichita mountains[2] indicate the discovery of gold as early as 1832. These mountains are located in the forbidden ground of the Kiowa and Comanche reservation in the southwestern part of the territory, and prospectors or miners are not allowed to explore the locality.

There are indications in many parts of the territory of the occurrence of coal, asphalt, zinc, lead, copper, iron, cobalt, mica, clay, and cement,[3] but no production of these minerals was reported in 1902. Coal has been obtained in small quantities in Pawnee county and in the Osage reservation, and is also known to occur in Payne, Lincoln, Logan, and Pottawatomie counties and in the Kiowa and Comanche reservation.

Deposits of copper occur near Kenton in the extreme western end of Beaver county; zinc and lead are found in several places in eastern Oklahoma and in the Kiowa and Comanche reservation; and asphalt is known to occur in Comanche and Kiowa counties, in some places even oozing from the ground. Natural gas in small quantities is found in Kay and Greer counties, but no profitable flow has been obtained.[4]

An excellent quality of dolomitic limestone is found in Blaine county and deposits of granitic rocks occur in the Wichita mountains. Cement is found in a number of localities, and beds of clay suitable for the manufacture of building and paving brick occur in various parts of the territory. Cobalt and iron ore are among the minerals reported by Lewis and Clarke in their exploration into this territory in 1803 to 1807.

The value of the products of those manufacturing industries based primarily on the products of mines and quarries is shown in Table 2 in comparison with the total value of products of all manufactures.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$7,083,938
Based upon products of mines or quarries:		
Clay, glass, and stone products	$252,072	
Iron and steel and their products	59,250	
Metals and metal products, other than iron and steel	123,418	
Miscellaneous industries	188,881	
		623,621
All other		6,460,317

As shown in the above table the manufactures of Oklahoma, based on the products of mines and quarries, represent but 8.8 per cent of the total of all manufactures. The mineral industry is insignificant when compared with manufacturing in the territory; the value of the product of mines, quarries, and wells in 1902 being only 2.6 per cent of the total obtained by combining the total value of manufactured products in 1900 with the total value of the products of mines, quarries, and wells in 1902.

At the Twelfth Census manufactures were reported as giving employment to 2,054 wage-earners who were paid $807,826 in wages. Mines and quarries in 1902

[1] Report of the Governor of Oklahoma, 1899, page 79.
[2] Ibid., 1903, page 69.
[3] Ibid., 1899, pages 78 and 79.
[4] Report of the Governor of Oklahoma, 1901, page 102.

employed 128 wage-earners and paid $64,545 in wages. Manufactures therefore contributed 94.1 per cent of the wage-earners of the two industries and paid 92.6 per cent of the wages, while mines and mining gave employment to 5.9 per cent of the wage-earners and paid 7.4 per cent of the wages.

Limestones and dolomites.—Quarrying operations for limestones and dolomites are extensively carried on in Kay county, which locality reports the only commercial production in 1902. The value of the output from the 12 productive quarries was $50,541. The stone was used principally for building, flagging, and curbing.

During 1901 the product of the limestone quarries was chiefly crushed stone used for railroad ballast, building purposes, etc., and was valued at $32,497.[1]

All other minerals.—One of the most promising natural products of Oklahoma is gypsum, for which a considerable development is reported during the past few years, due principally to the extension of railroads through the territory.[2] In 1852, in his account of this locality, Marcy made the statement that the discovery of gold in the Wichita mountains would attract more attention, but that the gypsum beds would be worth more than the gold.

Extending across the territory are great ledges of gypsum. In some places along the rivers and creeks, this soluble rock has succumbed to the action of the water, and caves, tunnels, natural bridges, and fantastic figures have been produced. Only the most convenient and advantageous outcrops have thus far been quarried.[3]

The following table, compiled from reports of the United States Geological Survey, shows the annual production of gypsum from 1898 to 1902:

[1] United States Geological Survey, "Mineral Resources of the United States," 1902, page 697.
[2] Ibid., page 906.
[3] Report of the Governor of Oklahoma, 1900, page 79.

TABLE 3.—*Annual production of gypsum: 1898 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Quantity (short tons).	Value.
1898	3,150	$12,000
1899	11,526	36,600
1900	18,437	60,380
1901	15,930	66,031
1902	34,156	111,215

In 1902 the territory's production of gypsum was quarried in the counties of Blaine, Caddo, Canadian, and Kay. The product is reported to be of the same character as that obtained in Kansas,[4] and it was all calcined as wall plaster or plaster of Paris. The first commercial production was reported in 1894, and amounted to 1,300 short tons valued at $7,500. No operations were reported during the next three years, but in 1898, 3,150 short tons were produced valued at $12,000, and since then there has been a steady increase.

Sandstone occurs as a surface rock in almost every county in Oklahoma, varying in texture from a coarse, rotten shale to a hard, fine grained stone.[3] The production in the territory for 1902 was all quarried in Logan county. It was used chiefly in the rough for foundations and similar building purposes, and also in small quantities as crushed stone for roadmaking.

There were three producing petroleum wells in the territory in 1902, all in Greer county. Two of them were drilled during the year. The petroleum is a heavy black lubricating oil, and it is found in hard, porous rock. Indications of large oil deposits occur in various parts of the territory,[5] notably in the Osage reservation and in Payne, Lincoln, Pottawatomie, Oklahoma, Comanche, and Kiowa counties.

Value of product	$2,087,389	$1,851,853	$160,075	$38,429	$20,133	$16,899

[1] Includes operators as follows: Borax, 1; copper, 2; gypsum, 1; nickel and cobalt, 1; sandstones and quartzites, 1.

In the Blue mountain region and the Rogue river section of the state are the principal gold producing localities. Although silver bearing ore is quite widely diffused, the production reported was principally obtained in the form of alloy with gold. The presence of more or less important coal deposits is indicated by outcroppings throughout the western and northwestern parts of the state and in Coos county. The deposits of stone promise unlimited supplies of building material.[1] Gypsum, used in making land plaster, occurs in Baker county; borax is found in Harney county; deposits of copper are known to exist in many portions of the state; and nickel ore occurs in Douglas county.

In addition to the production reported, valuable mineral deposits occur in many portions of the state. Some of these regions have been prospected or operated to a considerable extent, while others await only the advent of transportation facilities or the expenditure of sufficient capital in development to make them valuable workings. A synopsis of the principal of these known occurrences is herewith given, compiled chiefly from the facts given in the third revised edition of "The Resources of the State of Oregon," as collected and prepared by the state board of agriculture.

Antimony occurs in Jackson county, and asbestos of good fiber is found in the southern and eastern part of the state. Alkaline salts, potash, sodium, and niter, and also borax, for which a production is reported in 1902, are obtainable from lakes and springs in the arid region, east of the Cascades. Natural cement is reported in Douglas county and chrome iron ore or chromite in a condition of remarkable purity and in almost exhaustless quantity is being developed in the serpentine formations of Coos, Curry, Douglas, and Josephine counties. Clay is found in Clackamas, Clatsop, and Coos counties; glass sand exists in streams flowing from granite rocks; and graphite and infusorial earth are obtained in Jackson county.

Important deposits of iron ores exist, chiefly in basalt, in twelve counties, for the most part in the western half of the state, although occurrences are also noted in Umatilla and Grant counties in the Blue mountains. Lead is found in Clackamas, Grant, and Linn counties, principally as galena. Magnesite and other refractory minerals are obtainable, at least in small quantities, in the serpentine rocks of southern Oregon. Manganese ore occurs in Columbia county, in the northern part of the state; marble is found in Josephine and Wallowa counties, and platinum and iridium in lodes are believed to exist in the south, principally in Coos, Curry, and Douglas counties. Of the precious stones, jet has been found in Clatsop county, while opals, serpentine, and chrysoprase, generally useful for ornamental purposes and occasionally rising to the dignity of gems, have all been reported in the state. Quicksilver has been noted in Douglas and Jackson counties, and zinc is known to exist in the Cascade range in Lane and Linn counties, chiefly in the form of zinc blende.

Nonproductive development operations were carried on quite extensively in 1902, 192 operators reporting expenditures as follows: Salaries, $162,184; wages, $805,855; contract work, $75,594; cost of supplies and materials, $241,161; and miscellaneous expenses, $47,191. These operations are reported for gold and silver, quicksilver, and coal (bituminous), named in the order of the amount expended.

[1] The Resources of Oregon, pages 29 to 42.

The relative importance among manufactures of manufacturing industries closely allied to or based upon the mining industry, using as their raw material the product of mine or quarry, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$46,000,587
Based upon products of mines or quarries:		
Chemicals and allied products	$148,559	
Clay, glass, and stone products	524,697	
Iron and steel and their products	1,116,654	
Metals and metal products, other than iron and steel	893,657	
Miscellaneous industries	2,758,294	
		5,441,861
All other		40,558,726

As presented in the above table, the manufactures intimately related to mining and quarrying were valued at $5,441,861, which amount is about two and one-half times the total products of the mineral industry in the state and 11.8 per cent of the total of all manufactures. The product of mining and quarrying in 1902 was $2,087,389, or 4.3 per cent of the combined value of the product of manufactures in 1900 and of mines and quarries in 1902. Manufactures in 1900 gave employment to 17,236 wage-earners, who received $8,333,533 in wages. Mines and quarries in 1902 gave employment to 1,166 wage-earners and paid $1,033,075 in wages. Of the combined figures for the two industries—18,402 wage-earners and $9,366,608 paid in wages—manufactures gave employment to 93.7 per cent of the wage-earners and paid 89 per cent of the wages, while mines and quarries employed but 6.3 per cent of the wage-earners and paid 11 per cent of the wages.

The following table, compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals reported for the state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Gold.[1]	Coal, bituminous.	Silver.[1]	Siliceous crystalline rocks.	Limestones and dolomites.
1890	$1,100,000	$177,875	$96,969	$44,150	(2)
1891	1,640,000	155,478	297,374	3,000	(2)
1892	1,400,000	148,546	70,077	6,000	(2)
1893	1,645,300	164,500	15,257	11,255	$15,100
1894	2,113,356	183,914	10,351	4,993	(2)
1895	888,300	247,901	65,930	1,723	970
1896	1,251,000	294,564	78,998	2,449	1,600
1897	1,353,100	313,890	89,212	1,125	(2)
1898	1,177,600	212,184	168,081	(2)	7,480
1899	1,429,500	260,917	173,641	3,012	8,000

1902[4]	1,816,700	160,075	[3]49,449	38,429	20,133

[1] Estimates of the Director of the Mint, value of the refined product; silver at coining value. The values given in Table 1 are the values at the mine.
[2] Not reported separately.
[3] Commercial value.
[4] Census figures, except for gold and silver.

Table 3 shows that there was a slight decrease in mineral production during the past several years, siliceous crystalline rocks being the only industry reporting an increase over 1901. The gold production during 1902 was only slightly less than during the previous year and was considerably greater than that reported at the beginning of the decade.

Gold and silver.—Gold was discovered on the Coquille river in 1852 and along other streams in southern and eastern Oregon.[1] The Blue mountain region is the principal gold producing place, with the Rogue river section second in importance. Placer mining is more productive in the western, and quartz in the eastern part of the state. The first quartz mining was reported in 1860.

Silver bearing ore is quite widely diffused, but the percentage of the precious metal is often disappointing. The silver reported is principally obtained in the form of alloy with gold, but important discoveries in lodes have been prospected and promise well.

The annual production of gold and silver from 1891 to 1902 is given in the following table:

TABLE 4.—*Annual production of gold and silver: 1891 to 1902.*

[Reports of the Director of the Mint.]

YEAR.	Gold (fine ounces).[1]	Silver (fine ounces).[1]	YEAR.	Gold (fine ounces).[1]	Silver (fine ounces).[1]
1891	79,335	230,000	1897	65,456	69,000
1892	67,725	54,200	1898	56,966	130,000
1893	79,592	11,800	1899	69,152	134,300
1894	102,234	8,006	1900	81,980	115,400
1895	42,972	51,000	1901	87,950	160,100
1896	60,517	61,100	1902	87,881	93,300

[1] Estimates of the Director of the Mint are for the refined product.

Coal, bituminous.—The coal production is obtained principally from Coos county, where it has been mined since the early fifties.[1] Outcroppings indicate the existence of deposits throughout the western and northwestern parts of the state as well as in the Blue mountain region. The coal produced is mainly lignite, with an average of less than 50 per cent fixed carbon, a considerable proportion of water, and from 5 to 20 per cent of ash. Oregon coal is free burning and well adapted for steam and heating purposes, although it will not coke. The following table shows the annual production from 1885 to 1902:

TABLE 5.—*Annual production of coal, bituminous: 1885 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.	YEAR.	Short tons.
1885	50,000	1891	51,826	1897	107,289
1886	45,000	1892	34,661	1898	58,184
1887	37,696	1893	41,683	1899	86,888
1888	75,000	1894	47,521	1900	58,864

1890	61,514	1896	101,721	1902	65,648

[1] The Resources of Oregon, pages 29 to 42.

The annual product has varied considerably, the year of least production being 1892. The greatest production was reported in 1897; since that time a decreased product has been shown. In 1902 development operations were reported which indicated an increasing interest.

Siliceous crystalline rocks.—Rocks of volcanic origin predominate in the state; among them are the andesites, the true basalts, the trachytes, and the tufas or fragmentary rocks. In 1902 the entire production was reported from Baker, Benton, Gilliam, Jackson, Marion, Multnomah, and Union counties. It was valued at $38,429.

The production during 1902 showed a decided increase as compared with the years following 1890. This increase in 1902 is chiefly attributed to the more extensive use of the stone as a paving material and in roadmaking.

Limestones and dolomites.—Limestone deposits at present commercially worked occur in Baker and Wallowa counties in the northeastern, and Jackson and Josephine counties in the southwestern part of the state. In Grant and Union counties there are valuable deposits,[1] the latter county being covered to a large extent with blue limestone. During 1902 the entire production, valued at $20,133, was used in lime burning; in 1901 a value of $12,420 was reported for lime burning; in 1900, $10,525; and in 1899, $8,000. There was thus a steady increase in the use of limestone for this purpose. The comparatively large product shown for 1901 included a value of $12,100 quarried for paving and roadmaking, while during 1902 siliceous crystalline rocks were more extensively used as a paving material and no limestone was reported except for lime burning.

All other minerals.—The entire production of borax in 1902 was reported by one company in Harney county, although borax and various other alkaline soluble salts are found also in Klamath and Lake counties. The arid plains of this region are of late volcanic origin and contain lakes with no outlets, carrying useful salts in heavy solution. All the production reported was submitted to a process of crystallization before being marketed.

The copper produced is chiefly copper-glance and native copper, carrying gold, and it occurs chiefly in fissure veins. Deposits are known to exist in many parts of the state, notably the native ore and chalcopyrite of the Santiam region in Linn county, the sulphides of the eastern Oregon gold quartz mines, and the native copper of Union and Baker counties.[2] The 1902 production was reported by one company in Josephine county in southern Oregon, and was all reduced by smelting.

A considerable production of gypsum was reported in Baker county, none of which was sold in crude state, all being prepared as land plaster, wall or cement plaster, or plaster of Paris. As only one company was engaged in this production the statistics can not be given separately, because to do so would disclose the operations of an individual establishment.

Nickel ore occurs, in association with garnierite, chromite, magnetite, chrysoprase, chalcedonic quartz, and serpentine minerals, principally in Douglas county.[2] A small production was reported for 1902.

[1] Includes operators as follows: Crystalline quartz, 1; garnet, 1; graphite, 2; phosphate rock, 1; precious stones, 55 (no mines); talc and soapstone, 2.

The vast and varied mineral resources of Pennsylvania give the state first rank in the mineral industry of the country. The value of the output of the productive mineral properties of the state in 1902 was $236,871,417, or 29.7 per cent of the total value for the United States.

The most important of the state's mineral resources, from a commercial standpoint at least, are its coals. In its vast stores of anthracite coal, which underlie some 484 square miles,[1] Pennsylvania has a notable advantage over other states. There are three groups of parallel valleys in which these coal measures appear, the Northern, or Wyoming and Lackawanna valley, the Middle, or Lehigh and Mahanoy, and the Southern, from which the Lykens valley coal comes.[2] The bituminous coal fields which run in six parallel valleys[3] from New York to Ohio and West Virginia, underlie some 15,800 square miles of the state, and belong to the great Appalachian field, which also includes the coal regions of Ohio, Maryland, Virginia, West Virginia, eastern Kentucky, Tennessee, Georgia, and Alabama.[4]

The petroleum and natural-gas fields cover many square miles of the state's area, and in the combined values of petroleum and natural-gas production Pennsylvania leads among the states.

The Cornwall hills, in Lebanon county, are composed of and underlaid with magnetic iron ore forming one of the most wonderful deposits of this variety of ore in the world. Since 1740 nearly 9,000,000 tons of ore have been quarried from these beds. Fine brown hematite is taken from great open quarry mines in the central valleys and transported by rail to the iron works in the bituminous coal region beyond the Alleghenies and along the Lehigh and Schuylkill valleys.[5]

At Friedensville, in Lehigh county, are located the zinc mines which were opened in 1853, and were strong producers up to 1876.[6] On the Juniata, beds of hard,

[6] Ore Deposits of the United States, by James F. Kemp, page 175.

white, siliceous sandstone occur, large quantities of which are yearly used in glassmaking. The quarries at Slatington, in Lehigh county, produce vast quantities of the finest blue-black slate for billiard tables and mantels, blackboards and slates, flooring and roofing.[1]

The Gap mine, in Lancaster county, once the most important nickel mine in the country, was opened in 1718 and worked for copper until 1852, when the presence of nickel was discovered.[2] The mine is now shut down.

Marble of many varieties, from black to white, is found in the Great Valley, in Chester county, and has been quarried in immense quantities in Montgomery county. Serpentine, or greenstone, largely used in fine buildings, is quarried at Birmingham, and elsewhere in Chester and Delaware counties.[3]

Among other minerals in deposits of which the state is rich may be mentioned the following: The mineral paint, of Parryville; steatite or talc, of Schuylkill; fire clay and flagstones in several localities; the bluestone, of Tunkhannock and Meshoppen; chrome ore and graphite, of Chester county; silver bearing lead, formerly mined in large quantities in Chester county; sandstones, of Swatara and Schuylkill counties; whetstones, of Darby creek; granites, of Delaware and Philadelphia counties; and the kaolin, of Pennsburg and New Garden, used for making porcelain and china.[3]

The minerals found in the state, but which were not produced in commercial quantities in 1902, are chromite, gypsum, ilmenite, lead ore, manganese ore, nickel, platinum, rutile, strontium ore, and zinc.

In addition to the productive mines, quarries, and wells referred to in Table 1, there were 13 operators in 1902 who reported development work, mostly in connection with bituminous coal, natural gas, and slate properties. These operators paid their salaried officials, clerks, etc., $3,590 during the year, gave employment to an average of 44 wage-earners, and paid $20,752 in wages. The work done by contract amounted to $36,332, the miscellaneous expenses were $4,677, and the cost of supplies and materials was $39,216.

[1] King's Handbook of the United States, pages 725 and 726.
[2] The Mineral Industry, 1892, Vol. I, page 345.
[3] King's Handbook of the United States, page 726.

The following table shows the value of the output of manufactures, based primarily upon the products of mines and quarries, and also the value of all manufactured products of the state, as reported at the census of 1900:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$1,834,790,860
Based upon products of mines or quarries:		
Chemicals and allied products	$60,794,380	
Clay, glass, and stone products	57,386,453	
Iron and steel and their products	632,501,781	
Metals and metal products, other than iron and steel	35,504,249	
Miscellaneous industries	86,408,772	
		872,595,635
All other		962,195,225

As will be seen from the foregoing table, the value of the manufactures based primarily upon the products of mines and quarries was $872,595,635, or 47.6 per cent of that for all manufactured products of the state in 1900. The value of the output of the productive mines, quarries, and wells of the state for 1902 was $236,871,417, or 11.4 per cent of the combined value of manufactured products in 1900, and mine and quarry products in 1902.

The manufacturing industries of Pennsylvania, as reported at the Twelfth Census, employed 733,834 wage-earners during 1900 and paid $332,072,670 in wages. In 1902 the operators of the productive mining properties employed 190,935 wage-earners and paid $114,122,437 in wages. The two industries therefore employed a total of 924,769 wage-earners and paid $446,195,107 in wages. Manufactures employed 79.4 per cent of the wage-earners and paid 74.4 per cent of the wages, while mines and quarries employed 20.6 per cent of the wage-earners and paid 25.6 per cent of the wages.

The following table compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals of Pennsylvania from 1890 to 1902:

TABLE 3.—VALUE OF ANNUAL PRODUCTION OF PRINCIPAL MINERALS: 1890 to 1902.

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Coal, anthracite.	Petroleum.	Natural gas.	Cement.	Limestones and dolomites.	Slate.	Sandstones and quartzites.	Iron ore.	Siliceous crystalline rocks.

[1] Value not reported.
[2] Census figures.

Coal, bituminous.—The bituminous coal fields underlying an area of 15,800 square miles,[1] lie chiefly in the western part of the state, and spread from Ohio, West Virginia, and Maryland northeast toward New York.[2]

The Upper Carboniferous in the bituminous coal fields of Pennsylvania has been divided into the following five subdivisions in descending order: Dunkard, Monongahela, Conemaugh, Allegheny, and Pottsville. The principal sources of coal are the Allegheny and Monongahela formations, over 95 per cent of the output having been derived therefrom. Shipping mines are also located in the Pottsville and Conemaugh formations, the mines of the former being situated on the very extensive outcrop near the margins of the coal fields, while those of the latter are almost entirely confined to the area of this formation near the southern boundary of the state.[3]

The earliest recorded instance of the mining of bituminous coal in Pennsylvania was in 1760, when a coal mine was opened in the deposit along the Monongahela river, at a point opposite the site of the present city of Pittsburg. With the advent of the first steam engine in Pittsburg in 1794 the demand for this fuel increased, and by 1800 a number of mines were being worked on both sides of the river, the coal being used quite extensively in salt works, glass factories, and for general purposes.[3]

Coal was first shipped from Pittsburg in 1803, and in 1846 the shipments from this point down the Ohio river amounted to 214,000 tons. About 1842 commercial shipments from the Blossburg basin began, and a little later the Barclay basin was developed. During the same decade the use of the Sharon block coal in the Mercer county furnaces is said to have begun. The rapid development of the Cambria county coals practically began with the construction of the State Portage and Pennsylvania railroads, and shortly after the completion of the Low Grade division of the Allegheny Valley Railway in 1872 the notable development of the Reynoldsville basin began.[4]

In 1902 there were 1,023 productive bituminous coal mines in Pennsylvania, and the total output was 98,574,367 short tons, or 37.9 per cent of the production of bituminous coal in the United States. The value of this bituminous coal product was $106,032,460, or 44.8 per cent of the total value of all mineral products of the state and 13.3 per cent of the total for the United States in 1902.

Twenty-four counties in the state contributed to the production of this mineral. Among these, Fayette and Westmoreland, which contain the Connellsville coking region and which have stood for a number of years at the head of the bituminous coal producing counties, retained their supremacy, the former having a production of 18,988,058 tons, and the latter 18,811,511 tons. Allegheny county is third in rank, with 11,919,569 tons, and Cambria county, with 10,561,835 tons, ranked fourth.[5]

The following table, compiled from reports of the United States Geological Survey, shows the annual production of bituminous coal in Pennsylvania from 1840 to 1902:

TABLE 4.—*Annual production of coal, bituminous: 1840 to 1902.*

Coal, anthracite.—The anthracite coal region of Pennsylvania, situated in the eastern part of the state, embraces a territory of about 3,300 square miles, but only about 484 square miles is underlaid by workable coal measures. These measures are principally located in Lackawanna, Luzerne, Carbon, Schuylkill, and Northumberland counties, but are also found in Susquehanna, Sullivan, Columbia, Dauphin, Wayne, Wyoming, and Lebanon counties,[6] the last three mentioned, however, reporting no production in 1902.

The area is divided geographically into four divisions, known as the Northern, Eastern Middle, Western Middle, and Southern, and there is also a small basin in Sullivan county, known as the Western Northern or Loyalsock.[7] Of these fields, the Northern, also called the Wyoming, contains 200 square miles, or 34 per cent of all the workable coal area. This rich deposit, crescent in form, is 50 miles long and varies in width from

5.5 miles to diminishing points where the coal seams end. The extreme northern point of the crescent is in Susquehanna county, near Forest City, and the remainder of the region is in Lackawanna and Luzerne counties.[1] Since 1866 this region has been the leading shipper of coal.[2]

The Middle fields contain 130 square miles and their total length is 40 miles. These deposits lie principally in Luzerne county, but some sections are in Northumberland, Carbon, Schuylkill, and Columbia counties.[3]

The Southern field extends over 140 square miles and lies in Carbon, Schuylkill, and Dauphin counties. The greatest width is about 4 miles, at Pottsville, and the length is 55 miles.[3]

The first authentic record connected with anthracite coal history in the state is that in 1762 coal was discovered by the early pioneers in the Wyoming district, near the site of the present city of Wilkesbarre, and in 1769 it was first used by Obadiah Gore, a blacksmith. The presence of coal in the Schuylkill region was known in 1770, but the beds were not developed until 1834. From 1775 throughout the Revolutionary War anthracite coal, from the mines near Wilkesbarre, was shipped to the arsenal at Carlisle for use in the manufacture of war materials.[4]

Anthracite coal was first discovered in the Lehigh region, near Mauch Chunk, in 1791 and in the following year the Lehigh Coal Mine Company was formed and secured control of a large tract of coal land. It was not until 1802, however, that this company succeeded in floating coal laden arks down the Susquehanna and through the Lehigh and Delaware rivers to Philadelphia. Owing to the belief that the coal would not burn, no progress was made in the development of the coal trade for some years.[4]

In 1805–6 two brothers, by the name of Smith, settled in Plymouth, Pa., bought coal lands, and at once commenced shipping coal to points along the Susquehanna river, and although reports of the anthracite coal trade usually commence with 1820, when 365 tons of coal were shipped to Philadelphia from the Lehigh region, the real credit should be given to the Smith brothers, who had been shipping coal successfully for thirteen years prior to the date usually accepted as that beginning the record.

The trade from the Lehigh region was firmly established between 1820 and 1823. About 1825 the Schuylkill region was opened and in 1829 coal was being shipped from Carbondale.[5] From this time on the trade has rapidly increased until it has reached its present enormous proportions.

During the early days of anthracite coal mining a large percentage of the contents of the veins was not turned to commercial use. The methods of mining, transporting, and preparing were wasteful, and the operators were not economical in exploiting the veins, thinking them inexhaustible. In these early years of mining there was nothing to enforce economy in production, as the veins were rich, labor cheap, and prices comparatively high. These conditions existed until some years after the Civil War, when, owing to the diminution in profits, a more careful study was made of economical mining. Supplies were more carefully handled, the veins were operated more scientifically, and attention was given the great waste annually going on in the amount of coal sent to the dumps. Early in the fifties mining engineers in England had called attention to waste in mining, but it was not until many years later that mining engineers in this country turned their attention to the great waste in the anthracite coal fields. As a result of modern methods more coal is now being mined from the seams, better devices have been introduced in handling it, and better machinery put into the breaker.

A great economy in the use of coal was effected with a decrease in its size. Between 1870 and 1895 four or five sizes, theretofore unknown to the trade, were prepared for the market, and to-day they comprise 30 per cent of the coal shipped.

In 1890 attention was directed to the old culm heaps, so long such a disfiguring element in the coal regions. Previous to 1870 all sizes below chestnut were sent to the culm dump, and it has been estimated that in that year these dumps contained about 76,000,000 tons of marketable coal, and in the decade, 1870 to 1880, it has been estimated that about 19,500,000 more tons were thrown away. The matter of reclaiming the culm dumps was agitated. Despite opposition from many sources washeries were erected, and by the introduction of machinery, whereby still smaller sizes of coals could be prepared, a large percentage of the waste is now reclaimed and marketed.[6] The production of the 35 washeries reported at the census of 1902 amounted to 2,977,355 long tons.

In 1902 the 334 productive anthracite coal mines produced 36,940,710 long tons, the smallest annual production since 1886, while in 1901 the production was 60,242,560 tons. This decrease of 38.7 per cent was entirely caused by the strike in the anthracite regions, which lasted from May 12 to October 23, 1902.[7]

The following counties contributed to the state's output of anthracite coal for 1902: Carbon, Columbia, Dauphin, Lackawanna, Luzerne, Northumberland, Schuylkill, Sullivan, and Susquehanna. Among these Luzerne county ranked first in production, with

[6] The Anthracite Coal Industry, pages 213 to 227.
[7] Report on the Anthracite Coal Strike of 1902, page 37.

12,852,826 tons; Lackawanna second, with 10,779,268 tons; and Schuylkill third, with 7,704,202 tons.

The following table, compiled from reports of the United States Geological Survey, shows the annual production of anthracite coal from 1814 to 1902:

In connection with the discussion of past production, a consideration of probable future production is of great importance, and as bearing on this subject the following extract from the Report of the Anthracite Coal Strike Commission has been inserted:

According to the estimates of the Pennsylvania geological survey, the amount of workable anthracite coal originally in the ground was 19,500,000,000 tons. The production to the close of 1901, as previously stated, amounted to 1,350,000,000 long tons, which would indicate that there remained still available a total of 18,150,000,000 tons. Unfortunately, however, for every ton of coal mined and marketed 1½ tons, approximately, are either wasted or left in the ground as pillars for the protection of the workings, so that the actual yield of the beds is only about 40 per cent of the contents. Upon this basis the exhaustion to date has amounted to 3,375,000,000 tons. Deducting this from the original deposits, the amount of anthracite remaining in the ground at the close of 1901 is found to be, approximately, 16,125,000,000 tons. Upon the basis of 40 per cent recovery this would yield 6,450,000,000 long tons. The total production in 1901 was 60,242,560 long tons. If this rate of production were to continue steadily the fields would become exhausted in just about one hundred years.

Mr. William Griffith, in a series of articles contributed to the Bond Record in 1896, considers that the estimates upon which the foregoing computations have been made were too liberal. His estimates of the amount of minable coal remaining at the close of 1895 was 5,073,786,750 tons.[1]

In the six years from 1896 to 1901, inclusive, the production has been, approximately, 308,570,000 tons, which would leave still available for mining 4,765,216,750 tons. This supply, at the rate of production in 1901, would last a little less than eighty years. But as indicating how susceptible to error are human predictions, it is well to state that in his carefully prepared statement, published in 1896, Mr. Griffith assumes the limit of annual production would be reached in 1906, and would amount in that year to 60,000,000 tons.

This amount of production was reached in 1901, in just half the time predicted by Mr. Griffith, and the production of January, 1903, as recently reported, shows that the anthracite mines are capable of producing at a rate of 72,000,000 tons annually in their present state of development. It is not to be supposed, however, that the annual rate of anthracite production will continue practically uniform until the mines are exhausted and then suddenly cease. Portions of the fields have already been worked out, others are rapidly approaching total exhaustion, while others at the present rate of production will, it is calculated, last from seven hundred to eight hundred years. If we can assume the annual production will have reached its maximum limit at between 60,000,000 and 75,000,000 tons, and that the production will then fall off gradually as it increased, we may expect anthracite mining to continue for a period of from two hundred to two hundred and fifty years.

This estimate is based upon the assumption that the available coal will remain at about 40 per cent of the reserves. How much this may be increased by better mining methods and the utilization of former waste material it is impossible to say. Already a large amount of fuel is being recovered from the old culm banks, and it seems safe to predict that the coal saved will, in the near future, equal 50 per cent of the contents of the fields worked. However we may make our estimates of future production, it is apparent that the maximum output has been almost if not quite reached. The production henceforth will be from lower levels and thinner seams than those previously worked. This will necessitate greater expense in mining and, consequently, higher prices for the fuel. With higher prices will necessarily follow more economy in consumption, greater restriction of the market, and the increased competition of other fuels. All conditions seem to combine for the conservation of the supply of anthracite coal.

Petroleum.—The Indians are known to have collected what was called "Seneca oil" from petroleum springs, and the indications are that at a much earlier period the Mound Builders not only gathered the oil flowing from springs, but even dug wells in Pennsylvania and dipped up the petroleum.[2]

The earliest mention of petroleum in the state appears to have been in 1721, and on a map published in 1755 the word "petroleum" appears near the mouth of what is at present known as Oil creek, on the Allegheny river. From this time mention of the Seneca oil, naphtha, or rock oil, as it was variously called, became more frequent.[3]

The real beginning of the petroleum industry dates from the discovery in 1858 of Drake's well, near Titusville, in Crawford county. The success of this well, which produced 25 barrels daily, at that time an enormous quantity, occasioned a period of great excitement, and during 1859 and the next few years western Pennsylvania was a scene of indescribable activity and spec-

[1] Mr. Griffith's estimate includes all workable coal in the Northern field having beds 4 feet thick and yielding 3 feet of clean coal. In the other fields it includes seams 3 feet in thickness, capable of yielding 2¼ feet of clean coal. It excludes the culm piles, mine pillars, etc. The acreage of each bed is multiplied by the thickness of the seams in feet and thus reduced to foot-acres. Each foot-acre was estimated to produce 650 tons of coal, and on the 1st of January, 1896, the unworked areas were estimated to contain 7,805,826 foot-acres, or 5,073,786,750 tons.

[2] One Hundred Years of American Commerce, Vol. I, page 206.

[3] Transactions of the American Institute of Mining Engineers, Vol. VIII, pages 20 and 21.

ulation. Large numbers of wells were sunk along Oil creek, French creek, and the Allegheny river; adventurers flocked thither from all parts of the country, and what shortly became known as the "oil region" was transformed from an almost unbroken forest into camps and towns.

The first flowing well was struck early in 1861. Up to that time all of the oil was drawn from the wells by pumps. This well yielded 300 barrels per day and flowed for fifteen months. Soon after the largest flowing well ever operated in America, the Phillips, was struck, giving 3,000 barrels per day. The discovery of these "gushers" stimulated prospecting and enormously increased the production, with a corresponding decline in prices.

That the productive territory need not necessarily underlie the valleys and the river bottoms was demonstrated in 1862. In the succeeding years wells were struck on the high plateaus of Clarion, Butler, Armstrong, McKean, and Warren counties, the Clarion-Butler, or Southern, field being discovered in 1870.

In 1874 the great Bradford field was discovered. This field includes McKean county, Pa., and Allegany and Cattaraugus counties, N. Y., and has been one of the greatest oil producing fields in the history of the petroleum industry.

The other Pennsylvania oil fields are known as the Middle, including Warren and Forest counties; the Lower, or Southern, including Venango, Clarion, Butler, Beaver, and Lawrence counties; and the Washington, or Southwestern, including Allegheny, Washington, and Greene counties.[1]

For many years, in fact up to 1885, the Pennsylvania field, which includes New York, was looked upon as the undisputed source of supply of petroleum for the world,[2] and up to 1903 this field had produced 628,401,456 barrels, or 53.9 per cent of all the crude petroleum produced in the United States since 1859.

In 1891 the maximum annual output in the petroleum production of the state was reached. Since 1894 Ohio has surpassed Pennsylvania in the production of petroleum, and in 1902 the state ranked fifth, being outranked by Ohio, Texas, California, and West Virginia.[3]

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of petroleum from 1891 to 1902:

TABLE 6.—*Annual production of petroleum: 1891 to 1902.*

Natural gas.—The largest area of natural gas in the country lies within the state of Pennsylvania. The pools are thickly scattered to the west of an imaginary line drawn from the southeast corner of Greene county to the northeast corner of Potter county, including an area of about one-third of the entire state. The counties cut by this imaginary line and all to the west of it produce more or less natural gas.[4]

The presence of natural gas in Pennsylvania was undoubtedly known early in the eighteenth century, but the first recorded use of it in this country was in 1824, when a supply from a well was used to illuminate the village inn at Fredonia, New York.[5]

Early in the history of oil well drilling, which began in 1859, the gas which always escaped from oil wells was used as a fuel for firing the boilers on the drilling engines; it was soon being piped to houses for use as light and fuel. In 1872 the first natural gas plant was built, and a 2-inch line run from the Newton well to furnish gas for domestic purposes in Titusville, Pa., about five and one-half miles distant. It was not, however, until 1874 that the great value of natural gas as a manufacturing fuel was demonstrated. After that date its use rapidly increased until by 1890 it was estimated that natural gas had annually displaced as a fuel 10,000,000 tons of coal.[5]

Before the value of natural gas as a fuel was fully appreciated the extensive fields about Pittsburg had been discovered. The first well in this field was opened November 4, 1878, but no attempt was made to use the product of this well for four years, and very little drilling was done in the field until 1884.

About 1890 the territory south of Pittsburg began to be developed, although gas had already been discovered and used to a considerable extent in the vicinity of Washington, Washington county.

In the early days of the production of natural gas the original "rock" pressure of the wells was so great and the productive area so extensive that the supply was believed to be practically inexhaustible, and as a result it was wasted in the most extravagant manner. However, between 1885 and 1890 the earlier fields began to show unmistakable evidences of depletion. As a result the gas became more valuable and meters and other saving appliances were introduced.[6]

In 1902 the value of the natural gas produced in Pennsylvania amounted to $14,352,183, or 46.5 per cent of the value of the entire production in the country for that year. The product came from 5,408 wells. The 1902 production is the greatest in the history of the state since 1885, with the exception of 1888, when it reached its highest point.

Cement.—A large mass of cement rock of excellent quality was exposed near Williamsport, in Lycoming county, in 1831, during the construction of a canal

[1] The Mineral Industry, 1893, Vol. II, pages 509 to 511.

[6] Ibid., pages 476 and 477.

between Lock Haven, Clinton county, and Muncy, Lycoming county. A plant was immediately erected for the manufacture of such cement as should be required in the construction of the locks and dams of the canal, and until the completion of the canal this plant flourished. After this, however, the industry continued only in a small way, as the local demand for cement was not great. In 1850, during the construction of the Lehigh canal, from Easton, Northampton county, to Mauch Chunk, Carbon county, the cement rock, of which such large quantities have been used in this valley, was discovered.

The manufacture of cement for the Lehigh canal was commenced at Siegfried, in Northampton county, and the product proved to be of excellent quality. In 1865 a large natural rock cement establishment was erected at Coplay, in Lehigh county. While the product of this plant was of good quality, competition led to experiments in the manufacture of an artificial or Portland cement, and in 1870 a small quantity of this important material was produced. This was the first plant to successfully make Portland cement in this country. In 1878 there were four plants manufacturing cement on the Lehigh river. Their success was followed by a steady growth of the industry, and this locality became the leading center of production of artificial cement. This position it still holds, contributing more than one-half the entire output of the United States.[1]

The development of this industry was, however, comparatively slow, caused undoubtedly by the increased imports of artificial cement, and in 1891 the output of Portland cement from the 6 plants in Lehigh county reached only 268,500 barrels.[2] From this time on the annual production of Portland cement in Pennsylvania has steadily increased, and in 1902 it reached the highest point in its history. The production of Portland cement for that year in the United States was 16,691,055 barrels, of which Pennsylvania contributed 8,563,926 barrels, or 51.3 per cent.

Of the 17 productive plants in the state in 1902, 7 were located in Northampton county, 8 in Lehigh, and 1 each in Berks and Lawrence. Portland cement alone was manufactured by 11 of these plants, while the remaining 6 made both artificial and natural-rock cement, the production of the latter kind of cement amounting to but 796,876 barrels. The value of the entire cement production of the state was $10,223,267.

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of both Portland and natural-rock cement, from 1890 to 1902:

Limestones and dolomites.—Large quantities of gray or bluish gray stone, which because of its color and texture is unsuited to any form of ornamental work, are found in the Lower Silurian formations in Montgomery, Lancaster, and Chester counties. This stone has been extensively quarried for general building purposes and for foundations and bridge abutments. Limestone is also quarried for local use in Berks, Lebanon, Dauphin, Lancaster, York, and Cumberland counties, the Lancaster county stone being very durable. The stone quarried at York, in York county, is very fine grained, compact, and of a deep blue-black color, and if it were not uneven in texture might make a fine marble.[3]

In 1902 there were 907 limestone quarries in Pennsylvania, located in 43 different counties, among which Lawrence county was first in the value of its limestone production, Montgomery county was second, and Chester county third. The value of the limestone production in Pennsylvania in 1902 was $5,458,433, which gave the state first rank among the limestone producing states of the country. The value of the limestone quarried in the state for building purposes in this year amounted to $209,215, the balance of the production being used mainly for making lime, but also in road-making, railroad ballast, etc.

Slate.—Little is known of the beginning of American slate quarrying. Probably the first quarry opened was located in the Peach Bottom region in York county, Pa., about 1800. Another quarry was opened at Upper Mt. Bethel, Northampton county, in 1811, and the Franklin quarry located near Slatington, in Lehigh county, was being operated in 1846. On the southeastern side of the Blue or Kitatinny mountains, in Northampton county, is located the most important slate producing area of America.[4] This area forms a belt which extends throughout the entire northern part of Northampton and Lehigh counties and thence, in a gradually narrowing band, in a southwesterly direction through Berks, Lebanon, Dauphin, Cumberland, and Franklin counties.[5]

[3] Stones for Building and Decoration, by George P. Merrill, page 321.
[4] The Mineral Industry, 1897, Vol. VI, pages 593 to 595.
[5] Stones for Building and Decoration, pages 192 to 194.

This area has been divided into four regions—the Bangor, the Pen Argyl, the Lehigh, and the Hard Vein. Of these regions the Bangor is the most important, and the No. 1 Bangor slate is generally regarded as the standard in this country.[1] The slate of this region is soft and tough, and when free from ribbons is generally of high quality and noted for its durability. Aside from its use for roofing the material from the Bangor region is also used in making blackboards, school slates, and mantels. The slate of the Pen Argyl region closely resembles the Bangor slate. Almost the entire output is used for roofing purposes. In area the Lehigh region is the largest, and its output, besides being used for roofing purposes, also makes excellent blackboards. The slate from the Hard Vein region is harder than that from any of the other regions.[2]

In 1902 the 91 productive slate quarries of Pennsylvania were located in Northampton, Lehigh, and York counties. The total output of slate in the state for the year was valued at $3,547,322, of which $2,398,964, or 67.6 per cent, was contributed by Northampton county. Of the entire output the value of that used as roofing slate amounted to $3,001,545, the rest of the product being made into school slates, blackboards, mantels, tilings, etc.

In 1902 the output of slate in the United States amounted in value to $5,696,051, of which amount Pennsylvania contributed 62.3 per cent. In this branch of mineral industry Pennsylvania has long held first place.

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of roofing slate from 1884 to 1902:

TABLE 8.—*Annual production of roofing slate: 1884 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

1893	364,051		

[1] Not reported.

Sandstones and quartzites.—The principal quarry in the state in the belt of Triassic sandstone is located in Dauphin county. The texture of the rock is of medium fineness and the color is a deep bluish brown. The stone compares very favorably with any other Triassic stones and is now in very general use in all principal eastern cities.

The Carboniferous sandstones of Pennsylvania, although occasionally of good quality, are little quarried except for local use. The stones of Subcarboniferous formation have been but little quarried for purposes of construction, although at Franklin, in Venango county, a fine grained, evenly bedded buff stone, resembling to some extent the buff variety of the Berea grit, is quarried for sidewalks and buildings in the vicinity.

Aside from the Triassic stones those quarried from the Devonian formations are the most important. The stone from this formation, known as the Wyoming Valley stone, agrees very closely in general appearance with much of the bluestone quarried in New York state.[3]

The value of the output of sandstones and quartzites, including bluestones, quarried in Pennsylvania in 1902 amounted to $2,800,108, which gives to the state first rank in the production of this class of minerals. The 1902 production exceeded that for 1901 by $737,026.

Iron ore.—The magnetite variety of iron ore, as well as the red and brown hematites and the carbonate, is found in various localities within the state in deposits of more or less richness. The brown hematites are apparently divided into two series, starting in the northern section of the state, and running southwest in nearly parallel lines. The magnetites occur between these two belts. The carbonate variety of iron ore is found in the western portion of the state, and between the carbonate and the brown hematite belts are found the red hematites.[4]

The celebrated Cornwall mines of magnetic ore, containing one of the largest and richest deposits of this variety of iron ore in the country, are located in Lebanon county, 5 miles south of Lebanon and about midway between Reading, on the Schuylkill river, and Harrisburg, on the Susquehanna.[5] The area of ore here exposed measures about 4,000 feet in a direction nearly east and west, with a breadth of from 400 to 800 feet, and includes three hills, separated by two valleys, running north and south. These mines have been among the most productive iron ore properties in the country, having produced up to 1889 over 10,000,000 tons.[6]

The limestones of the Cumberland valley are very rich in limonite, or brown hematite ores, which form a large part of the charges of the many blast furnaces situated on their outcrops. The mines from which these ores are obtained are really only pits or quarries, the ores being extracted by means of picks and shovels.[7]

While the presence of iron ore in Pennsylvania was undoubtedly known at an early date, it is not probable that any deposits were developed to any considerable extent until the latter part of the seventeenth or the early years of the eighteenth century.

[7] Transactions of the American Institute of Mining Engineers, Vol. III, page 410.

The first recorded instance of the manufacture of iron within the state was in 1692, and the first successful ironworks were established in 1716, on Manatawny creek, in Berks county.[1] In the same year the development of the iron ore mines of the Schuylkill valley began.[2] About 1720, a furnace, located in the heart of one of the richest deposits of magnetic iron ore in the country, was erected on Ironstone creek, Colebrookdale township, in Berks county.[3] The celebrated deposits of magnetic iron ore of Cornwall hills are said to have been worked about 1735,[2] and in 1742 the Cornwall furnace was built. The mine was described, a few years later, as being rich and abundant. During the War of the Revolution, Cornwall furnace cast cannon and shot and shell for the Continental Army, and it was still in operation as late as 1882.[4]

In 1902 there were 42 operators in Pennsylvania who reported 47 productive iron mines, having an output of 822,932 long tons, which gave to the state sixth rank in quantity of iron ore produced.

In the output of the different varieties of iron ores the state ranks first in magnetite, with a production of 616,645 tons; sixth in brown hematite, with 185,846 tons; and twelfth in red hematite, with 20,441 tons.[5]

In 1902 the following counties contributed to the state's output: Berks, Bucks, Center, Cumberland, Huntingdon, Lancaster, Lebanon, Lehigh, Northampton, Perry, Snyder, Union, and York. Among these Lebanon county ranks first, with 594,177 tons, or 72.2 per cent of the state's production, drawn entirely, in 1902, from the celebrated Cornwall mine. Center county ranks second with a production of 64,382 tons, and Lehigh county third with 58,508 tons.

Pennsylvania showed a decrease of 217,752 tons in the production of iron ore in 1902, as compared with 1901. The value of the state's production was $1,225,453, or an average value of $1.49 per ton.

The following table, compiled from reports of the United States Geological Survey, shows the annual production of iron ore from 1889 to 1902:

TABLE 9.—*Annual production of iron ore: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Long tons.	YEAR.	Long tons.
1889	1,560,234	1896	747,784
1890	1,361,622	1897	723,742
1891	1,272,928	1898	773,082
1892	1,084,047	1899	1,009,327
1893	697,985	1900	877,684
1894	532,087	1901	1,040,684
1895	900,340	1902	822,932

Siliceous crystalline rocks.—Although Pennsylvania leads among the stone producing states, it furnishes comparatively little in the way of granitic rock. Nearly all of the granite quarries in the state are in the district extending from the Delaware river, at Trenton, to the state line, near the Susquehanna, thus lying south of the limestone valley of Montgomery county. The largest of these quarries are in the vicinity of Philadelphia, and the product, which is for the most part a dark gray hornblende gneiss, is used particularly for the rough work of foundations.[6]

In 1902 siliceous crystalline rocks were quarried in Adams, Berks, Bucks, Chester, Delaware, Fayette, Lancaster, Lehigh, Montgomery, and Philadelphia counties, the total output amounting in value to $661,062. Among the counties referred to, Berks ranks first in the output of this rock, Delaware second, and Philadelphia third.

Clay.—The refractory clays and shales of the coal measures of Pennsylvania constitute one of its most important mineral resources, especially in the western part of the state. Among the more important of these are the Bolivar fire clay, under the upper Freeport Coal Measures, and a fire clay in Beaver county, underlying the Kittanning coal. Another important bed occurs in Indiana, Cambria, and Beaver counties.[7]

The deposits of kaolin near Brandywine Summit, in Delaware county, contain some of the oldest mines in the country. In southeastern Pennsylvania the decay of schistose or limestone rocks at the contact of the Cambrian and Silurian has yielded some white residual clays which, after washing, are suitable for white earthenware manufacture.[8]

In the manufacture of brick and tile Pennsylvania leads, but in the production of clay products as a whole the state ranks second. In 1902 clay was produced in the state by 13 counties, and was valued at $288,811.

The following table, compiled from reports of the United States Geological Survey, shows the annual production of clay from 1900 to 1902:

TABLE 10.—*Annual production of clay: 1900 to 1902.*

YEAR.	Short tons.
1900	140,734
1901	144,547
1902	161,546

Mineral pigments, crude.—The mineral substances included under this heading are the ores used in the manufacture of metallic paint, such as ocher, umber, sienna, venetian red, etc.

The "paint bed" at Lehighgap was discovered in 1856. This bed outcrops along the southern border of

[8] The Clays of the United States East of the Mississippi River, by Henrich Ries, page 49.

Carbon county, about 27 miles north of Bethlehem, in a well defined ridge of Oriskany sandstone, known as Stony Ridge. The bed, however, is not continuous throughout the extent of this ridge. The ore is bluish gray, resembling limestone, and is very hard and compact.[1]

In 1902 there were 12 mines in Pennsylvania which produced crude mineral pigments, located in the counties of Berks, Carbon, Lawrence, Lehigh, Lycoming, Luzerne, Montgomery, Northampton, and Wyoming. The output amounted to 20,807 short tons, valued at $246,346. Carbon county was the greatest contributor to this total, with Lehigh county next, and Northampton county third. The production for the United States amounted to 35,479 short tons, of which Pennsylvania contributed 58.6 per cent.

Silica sand.—The glass sand mined in Pennsylvania in 1902 came from the counties of Berks, Butler, Chester, Fayette, Lancaster, Lebanon, Mifflin, Somerset, and Westmoreland. It occurs both as a sandstone, which requires crushing and preparation before use, and as a sand, which quickly disintegrates when quarried and exposed to air and moisture.[2]

The output of silica sand in the state in 1902 was 268,262 short tons, of which Mifflin county contributed 76,000 tons, or 28.3 per cent, leading the remaining eight counties producing this mineral. The state's output was 60.2 per cent of that for the United States, which was 445,903 short tons.

Marble.—The only quarries of merchantable marble at present worked within Pennsylvania lie in the belt of Lower Silurian limestone, which extends from Sadsbury, in Lancaster county, in an easterly direction through Chester county, and through the western half of Montgomery county. The prevailing colors of the stone throughout the larger portion of this area are yellowish or bluish, and as a consequence are suitable only for making quicklime or for ordinary rough building purposes.[3]

Quarries were first opened in Montgomery county about the time of the Revolution, and up to 1840 this stone was almost the only material used in the better class of stone buildings in and about Philadelphia. Increased transportation facilities about this date brought the better varieties of eastern marbles into the Philadelphia market, and as a consequence the Montgomery county marble was not in as great demand.[3]

In 1902 there were only three productive quarries in the state, located one each in Chester, Dauphin, and Montgomery counties. The value of the output from these quarries was $160,423; of this amount $110,977 represented the value of that which was dressed for building purposes, and $24,000 that dressed for monumental purposes.

Feldspar.—Pennsylvania is one of the leading states in the production of feldspar, large deposits of this mineral occurring in the serpentines of Chester county and in the granitic rocks of Delaware county. Nearly all the feldspar quarries are worked as open pits, but in a few instances underground tunnels have been employed. The largest quarry is located near Elam, in Delaware county, and has been productive since 1883. This quarry has been worked to a depth of 100 feet, with some underground workings extending 300 feet or more along a vein which the open working shows to be 60 to 70 feet wide.[4]

In 1902 there were twelve productive feldspar quarries in the state, all of which were located in Chester and Delaware counties. The entire output amounted to 15,121 short tons, or 33.4 per cent of the production of the United States for 1902. The value of the state's output amounted to $115,699.

All other minerals.—The American millstone varies from a sandstone to a quartz conglomerate, and the rock from which it is made occurs along the eastern slopes of the Appalachian mountains from New York to North Carolina, and is known by various names.[5] In Pennsylvania it is called "Cocalico," and is found in Lancaster county. The three productive quarries in 1902 had an output valued at $1,978.

The crystalline quartz produced in Pennsylvania in 1902 came from Chester county and was largely used in the manufacture of sandpaper. No figures can be shown for the single operator without disclosing individual operations.

The mineral worked throughout the entire Appalachian region, either for pottery or under the name of "flint," and included in this report is quartz. It is used chiefly in the manufacture of pottery and porcelain, although some of it is used in soapmaking and wood fillers. The four productive quarries of the state in 1902 were located in Adams, Chester, and Lancaster counties, and had an output valued at $42,721, or 29.6 per cent of that for the United States.

The garnet found in Pennsylvania is of the ruby or rose colored variety, and is used by the manufacturers of shoes as an abrasive. The deposits are found in Delaware county and occur in a quartzose gneiss.[6] There was but one operator in the state in 1902.

Graphite is produced commercially only in Chester and Berks counties. In the mine near Chester Springs,

[1] Transactions of the American Institute of Mining Engineers, Vol. XIX, pages 322 to 325.

[4] The Mineral Industry, 1898, Vol. VII, pages 267 and 268.
[5] United States Geological Survey, "Mineral Resources of the United States," 1902, pages 878 and 879.
[6] The Mineral Industry, 1897, Vol. VI, page 21.

in Chester county, the mineral occurs in two layers of disintegrated mica schist, and the rock is so distinguished that most of the graphite material can be removed without blasting. In 1902 both the productive properties were located in Chester county.[1]

The output of the phosphate rock mines of Pennsylvania, located in Juniata county, was first reported in 1899 by the United States Geological Survey, and amounted to 2,000 tons, valued at $9,000. In 1902 there was but one operator.

The value of the output classed under "precious stones" was $5,000, and consisted of specimens of anthracite and iron ore suitable for making into ornaments.

The two soapstone quarries of the state productive in 1902 were located in Montgomery and Northampton counties; the output is put on the market as ground talc.

[1] The Mineral Industry, 1901, Vol. X, page 369.

RHODE ISLAND.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Rhode Island for 1902.

TABLE 1.—*Summary: 1902.*

	Total.	Siliceous crystalline rocks.	All other minerals.[1]
Number of mines or quarries	22	19	3
Number of operators	22	19	3
Salaried officials, clerks, etc.:			
Number	56	54	2
Salaries	$56,150	$55,310	$840
Wage-earners:			
Average number	667	638	29
Wages	$435,224	$421,608	$13,616
Miscellaneous expenses	$25,938	$22,898	$3,040
Cost of supplies and materials	$85,127	$71,908	$13,219
Value of product	$774,611	$734,623	$39,988

[1] Includes operators as follows: Graphite, 1; limestones and dolomites, 2.

Rhode Island has held for many years a very prominent position among granite producing states on account of the superiority of its granite for monumental purposes, particularly the stone that is quarried at Westerly and vicinity.[1]

In previous years some coal which was classed as anthracite was mined in the eastern part of the state. This product is not in reality an anthracite coal, but is graphitic, and, in the last few years, has been included with the graphite production.[2] It is of a structure between scaly and granular, and contains, in selected samples, as much as 52 per cent carbon.[3]

The following minerals also occur in the state, but were not mined in commercial quantities in 1902: Asbestos, galenite, garnet, iron ore, talc and soapstone, whetstones, copper pyrite, sandstone, manganese ore, agate, jasper, and molybdenum in Providence county, and serpentine in Providence and Newport counties.[4] Deposits of ilmenite, mica, monazite, and rutile also occur, but were not exploited in 1902.

The following table shows for 1900 the value of the products of manufactures closely allied to or based upon the products of mines and quarries, and also the total value of all manufactures for the year:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$184,074,378
Based upon products of mines or quarries:		
Chemicals and allied products	$871,485	
Clay, glass, and stone products	1,430,960	
Iron and steel and their products	18,107,330	
Metals and metal products, other than iron and steel	22,752,825	
Miscellaneous industries	8,021,006	
		51,183,606
All other		132,890,772

The value of the products of the manufacturing industries of the state for 1900, as shown in Table 2, was $184,074,378, to which amount those branches based primarily on the products of mines and quarries contributed $51,183,606, or 27.8 per cent. During the same year 98,813 wage-earners, receiving $41,114,084, were employed in all branches of manufacture. In 1902 the mines and quarries gave employment to 667 wage-earners, who were paid $435,224 in wages. The combined industries, therefore, gave employment to 99,480 wage-earners and paid $41,549,308 in wages. Manufactures contributed 99.3 per cent of the wage-earners and 99 per cent of the wages, while mines and quarries contributed seven-tenths of 1 per cent of the wage-earners and 1 per cent of the wages.

The following table shows the value of the state's annual production of siliceous crystalline rocks from 1890 to 1902:

TABLE 3.—*Value of annual production of siliceous crystalline rocks: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Value.	YEAR.	Value.
1890	$931,216	1897	$629,564
1891	750,000	1898	320,242
1892	600,000	1899	400,128
1893	509,799	1900	444,316
1894	1,211,439	1901	501,698
1895	968,473	1902	734,623
1896	746,277

[3] Ibid., page 977.
[4] Ibid., 1887, page 785.

Siliceous crystalline rocks.—The mineral wealth of the state consists principally in its deposits of granite, which for the most part lie west of the bay in Providence, Kent, and Washington counties, although some stone is quarried in Newport county. Beginning in 1890 with an output valued at $931,216, the production decreased steadily until 1893; then increased in 1894 to $1,211,439, the maximum in the history of the state. The value of the output decreased again gradually until 1898, when the lowest value, $320,242, in the last thirteen years was reached. Since 1898 there has been again a gradual increase, the value in 1902 amounting to $734,623. This output was obtained from 19 quarries, 9 of which were located in Washington county, 6 in Providence, 3 in Newport, and 1 in Kent. The quarries in Washington county produced the greater part of the monumental stone of the state, 8 of the 9 quarries in this county showing this class of granite as their principal product. The output of the remaining quarries of the state was used chiefly for building stone, but some was also used as paving, curbing, and crushed stone for roadmaking and concrete, and some was sold as riprap and rubble stone.

The value of the stone used for monumental work in 1902 was $550,719, or 75 per cent of the total, and in 1901, $291,805, or 58.2 per cent of the total value for that year. For the years 1898, 1899, and 1900 no separation was made of rough stone, but the chief product was dressed stone for monumental work.

The importance of the state as a producer of monumental stone from 1898 to 1902 is shown in Table 4.

TABLE 4.—*Value of granite for monumental work for the United States and for Rhode Island, and per cent that Rhode Island forms of the United States: 1898 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	United States.	Rhode Island.	Per cent of total.
1898	$1,462,598	$204,739	14.0
1899	1,687,967	145,001	8.6
1900	1,598,842	232,144	14.5
1901	2,715,225	291,805	10.7
1902	3,998,911	550,719	13.8

The state, in 1898, was exceeded in value of its output of monumental stone only by Vermont and New Hampshire; its production was 14 per cent of the value for the United States. In 1899 the value of the production was 8.6 per cent of the total for all states, Rhode Island ranking fourth, being exceeded by Vermont, Massachusetts, and New Hampshire. In 1900, 1901, and 1902 the state ranked third, producing for the three years respectively 14.5, 10.7, and 13.8 per cent of the production of monumental stone in the United States. Vermont and New Hampshire led Rhode Island in 1900; Vermont and Massachusetts in 1901 and 1902.

All other minerals.—The only producer of graphite in the state is the Rhode Island Graphite Company, of Providence. The output has been combined with that of limestones and dolomites to avoid disclosing the operations of any single establishment.

Only two limestone quarries reported production in 1902, both located at Limerock, in Providence county. Almost the entire product was consumed in lime manufacture, though a small quantity was used for fluxing purposes.

SOUTH CAROLINA.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of South Carolina for 1902.

TABLE 1.—*Summary: 1902.*

	Total.	Phosphate rock.	Siliceous crystalline rocks.	Clay.	All other minerals.[1]
Number of mines or quarries	38	10	15	8	5

Miscellaneous expenses	$109,890	$65,157	$34,047	$3,185	$7,501
Cost of supplies and materials	$342,379	$162,836	$131,771	$11,612	$36,160
Value of products	$1,834,134	$950,208	$598,848	$107,325	$177,753

[1] Includes operators as follows: Gold and silver, 3; limestones and dolomites, 1; manganese ore, 1; precious stones, 5 (no mines).

The state ranked thirty-ninth in 1902 in the value of products of mines and quarries, with a total of $1,834,134. The range of mineral industry is confined in the main to three or four different products. Notable among these is phosphate rock, in the mining of which the state still takes high rank, though in former years it furnished nearly all of the production in the United States. Granite of high grade is found in abundance, and the kaolin beds of Aiken county are extensively worked. Gold ore, while not distributed over a wide area, is successfully mined.

Among the minerals of the state which were not mined commercially in 1902 are the following: Asbestos occurs near Glenn Springs and Cedar Springs in Spartanburg county, and in Pickens county. Fuller's earth is found in white, gray, yellow, pink, and black. The deposits extend in a broken, sinuous band across almost the entire state, and in some localities they approximate 40 feet in thickness.[1] Graphite has been found in the northeast corner of Spartanburg county and at Paris mountain in Greenville county. Iron ores occur in many sections of the northern and northwestern part of the state, many of the banks having been worked. The counties in which the principal deposits are located are York, Union, Spartanburg, Greenville, Abbeville, Lexington, Pickens, and Chesterfield. Iron pyrites are abundant in Spartanburg and York counties, and occur also in Chesterfield and Lancaster. Monazite has been found and mined in the extreme northern part of the state, especially in Spartanburg county. Talc is found in Abbeville, Lexington, Chester (where it has been worked), Anderson, Spartanburg, Union, and Pickens counties. Other minerals occurring in the state in varying quantities are: Bismuth, ocher, copper, pyrites, galena, brown coal, malachite, phosphate of lead, and barytes.[2]

The relative importance of manufacturing industries closely allied to or based on mining industry using as raw material the products of the mine or quarry is shown in the following table:

TABLE 2.—*Manufactures based primarily upon products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$58,748,731
Based upon the products of mines or quarries:		
Chemicals and allied products	$4,882,506	
Clay, glass, and stone products	888,935	
Iron and steel and their products	412,493	
Metals and metal products, other than iron and steel	291,845	
Miscellaneous industries	596,535	
		7,072,314
All other		51,676,417

The total value of the products of the manufacturing industries based primarily upon mining and quarrying was, as shown by Table 2, $7,072,314, or 12 per cent of the total value of the product of all manufacturing industries in the state in 1900. The value of the output of the mines and quarries of the state in 1902 was $1,834,134, or 3.1 per cent of the combined value of the product of manufacturing and mining. In 1900 there were employed in all branches of manufactures 48,135 wage-earners, who were paid $9,455,900 in wages. In 1902 there were employed in the mines and quarries 2,694 wage-earners, who received $891,737 in wages. By

[1] Clays of South Carolina, by Earle Sloan, page 60.

[2] United States Geological Survey, "Mineral Resources of the United States," 1887, page 786 ff.

combining the figures of these two branches of industry and comparing, it is disclosed that 94.7 per cent of the wage-earners, receiving 91.4 per cent of the wages, were employed in manufacturing, while 5.3 per cent of the wage-earners, receiving 8.6 per cent of the wages, were employed in mining.

The following table shows the value of the annual production of the principal minerals of the state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Phosphate rock.	Siliceous crystalline rocks.	Clay.
1890	$2,875,605	$47,614	(1)
1891	2,948,138	50,000	(1)
1892	1,877,709	60,000	(1)
1893	2,157,014	95,443	(1)
1894	1,745,576	45,899	(1)

[1] Not reported separately. [2] Census figures.

Phosphate rock.—The phosphate rock belt of the state is 70 miles long and 30 miles wide, extending from the mouth of the Broad river, near Port Royal, in the southeast, to the headwaters of the Wando river in the northeast. Its major axis is parallel with the coast, and its greatest width is in the neighborhood of Charleston.[1] The principal deposits are located in Berkeley, Dorchester, Charleston, Colleton, and Beaufort counties.[2] So far as occurrence in commercial quantities is concerned, their distribution is confined within narrow limits. They are found at the bottom of rivers, 20 to 30 feet in depth, and on land they occur at an elevation but slightly above mean tide. The rock of commerce occurs always above the marl and is known as land or water rock, according to its location. The water rock is darker in color and harder than the land rock, and is frequently found in a layer or sheet of cemented or tightly compacted nodules overlying the marls at the bottom of rivers and creeks, where it either forms the bottom itself or is overlaid by a deposit of mud of greater or less depth. The land rock is found generally at a depth of from 2 to 10 feet below the surface of the soil. It occurs in masses or nodules varying in size from that of a potato to several feet in diameter. These nodules are rounded, rough, indented, and frequently perforated with irregular cavities, and in color they vary from olive or bluish black to a yellowish or grayish white. By analysis they are found to contain 55 to 61 per cent of phosphate of lime, 5 to 10 per cent of carbonate of lime, 2 to 10 per cent of organic matter and water, with small quantities of fluorine, iron, magnesia, alumina, sulphuric acid, and sand. This land rock is found in a loose layer varying from a few inches to 30 feet in depth, and averaging about 8 inches. It occurs in sand, mud, clay, or peat, and is often intermingled with numerous remains of land and marine animals. Among the former are the bones of the mastodon, elephant, tapir, deer, and the domestic animals, the horse, cow, and the hog.[3]

The great bed, or series of beds, of phosphate rock which was later destined to supply the civilized world with the chief part of all the phosphate of lime used in the manufacture of commercial fertilizers was discovered, or rather its value was first definitely established, in 1867.[4] To Dr. St. Julian Ravenel, of Charleston, this honor has been accredited. However, forty years before, Robert Mills forecasted this discovery, saying, that "besides gypsum, we may also expect to find in that part of the state (the Atlantic seaboard), the same kind of marl which has so greatly contributed to enhance the value of the poor lands of New Jersey, by the fertility which it imparts to the soil."[5]

At the close of the Civil War Dr. N. A. Pratt, of Georgia, formerly connected with the Niter Bureau of the Confederacy, visited Charleston with the object of starting sulphuric acid chambers. His attention was directed by Doctor Ravenel, who had already noted the presence of phosphate of lime in considerable quantity in the marl stones, or nodules, near Charleston, to samples of the rock taken from the Ashley river region. Doctor Pratt analyzed the specimens and found that the rocks contained a sufficiently high percentage of phosphate of lime to render them of merchantable value.[6] As soon as the commercial importance of the deposits became generally known other available beds were located, and considerable capital was employed in developing the industry by mining the crude rock, and exporting the product or manufacturing it into superphosphates. Later the beds of many navigable streams were found to be largely paved with the valuable substance. In 1870 the mining for this river rock began, and was developed through the introduction of dredging and grappling apparatus into an industry of equal importance with the mining of the rock on land.[7]

[1] Seven months.

From the first the industry yielded large profits, and for a period of two and a half decades was prosecuted with great energy. Beginning with a production of 6 long tons in 1867, it had increased in 1877 to 163,000 tons, and ten years later to 480,558 tons, reaching the maximum in 1889, with 541,645 tons. In 1890 the output from the Florida mines had so increased that the condition of the industry in South Carolina became serious, and by 1892 what was once at a premium became a drug. The Florida developments had not only caused an overproduction of high-grade rock, but had forced upon the market immense quantities of lower grades, which could be used without any enriching material. The reason why 75 per cent and 80 per cent rock should retain an exceptional value no longer existed, and so it sank to a common level with the poorer products.[1] The adoption by the phosphate miners of the state of desperate measures to stem the tide and shut off competition by cutting the prices, only resulted in further embarrassment, until the market price dropped below the cost of production, and it became possible for them to remain in the market only by selling at a very tangible loss.[2]

The industry received further setbacks through a royalty dispute between the state and river miners and through a cyclone, August 27, 1893, which severely injured the mining plants, especially those of the river miners at Beaufort.[3] Barring a temporary setback in 1900 to the industry in the state, due mainly to scarcity of transportation facilities and high ocean freights, a gradual recovery has continued up to the present year.[4]

Siliceous crystalline rocks.—The granites and gneisses are widely distributed and extensively quarried above the fall line. The term granite is generally applied to all these rocks by the miners of the state. The granites proper are found in abundance and their outcrops lie along three nearly parallel lines. On the most southern of these lines they show themselves among the sand hills at Graniteville on Horse creek, Aiken county, and thence at various points, in a northeasterly direction, to Columbia. Many years ago notable quarries for building materials began to be worked on this line at Graniteville and at points in Richland county.[5]

The second line of outcrop extends from the neighborhood of Harris creek, Edgefield county, across Newberry, Fairfield, and Kershaw counties to the northwestern corner of Chesterfield. Here, also, quarries of excellent granite, fine grained and easy splitting, have been found, especially in Newberry and Fairfield counties, where there are inexhaustible quantities of the best building granite. A flesh colored porphyritic granite is found in Kershaw. In Edgefield and Lancaster counties it becomes coarser and syenitic in character. The third line of outcrop stretches through Laurens, Union, and York counties. In the vicinity of Union the granite is of exceedingly fine grain and well adapted for architectural purposes, but most of it on this line is characterized by a coarse porphyried structure.[5] Granite quarrying is an important industry in the state, being exceeded in value of product only by the mining of phosphate rock.

Clay.—Clays of many varieties are found widely distributed and constitute perhaps its greatest actual and prospective resource, being susceptible of greater extension and development than any other mineral.[6] The clays were among the first in the United States to attract attention, and early in the nineteenth century, prior to 1826, a Doctor Garden carried a small shipment of South Carolina kaolin to England and manufactured it into china ware.[7] While common, or brick, clay of excellent quality is found in almost every neighborhood, the state's principal wealth in clays lies in the extensive deposits of kaolin remarkable for purity. The sedimentary kaolins are widely distributed in the Savannah river area, the Santee area, and the Edisto area, in the counties of Aiken, Lexington, Richland, and Kershaw. In this region there are extensive beds of pure white kaolin exceeding 18 feet in thickness, and affording 98 per cent of clay substance, which requires no other preparation than drying.[8]

The Savannah river area affords perhaps the most remarkable exposures of sedimentary kaolin in the United States. In some places they are practically continuous for miles. From Hamburg to Aiken extends a zone 14 miles long by 5 miles wide.[9] The beds vary from 5 to 25 feet in thickness with an overburden of

[9] Ibid., pages 49, 50, and 81.

cross-bedded sands, thin layers of clay, and occasional Lafayette loams and cobbles, ranging in thickness from almost nothing to more than 100 feet. The thickness of the kaolin determines the amount of overburden that can be economically removed. This overburden is degraded by laborers with pick, shovel, and cart, or with scrapes or steam shovels until a sufficient terrace of clay is bared for extraction. The kaolin is moved in lump form to the dry sheds, where, after exposure to air and light for a few weeks, it is packed in casks of 1 ton capacity and shipped to the consumer. These deposits probably represent the largest body of clay closely approximating kaolinite to be found in the United States.[1]

In the Savannah river area of the coastal plain outside of the distinctive clay zone pertaining to the Cretaceous and Eocene formations, there are beds of clay of economic importance. At North Augusta and Hamburg a large deposit of alluvial clays occurs, which is excellently adapted to the manufacture of brick and the coarser stonewares.[2] A zone of older clays occurs approximately parallel with and about 30 miles distant from the coast. These clays are often fine grained and vary in color from pale yellow to a mottled blue; they are associated in many instances with coarse sands. Their average elevation above the sea level is 60 feet. These beds are developed near Garnett, and are adapted to the manufacture of tiling, face brick, and common brick.[2]

All other minerals.—The gold belt extends from the North Carolina border, southwest across the counties of York, Lancaster, Chesterfield, Kershaw, Fairfield, Chester, Spartanburg, Greenville, Pickens, and Abbeville. Auriferous gravels are found in many localities, but chiefly in York, Union, and Spartanburg counties.[3] The first consignment of gold from the sands of this state reached the United States Mint in the latter part of 1829.[4] The first recorded discovery of gold in the state, however, antedates this by three years, and was made in the Abbeville and Spartanburg districts.[5] In 1830 and 1831 numerous workings were under way in the state, especially in Lancaster and Chesterfield counties, where, in the latter, at the Brewer mine, even at this early date, from 100 to 200 men were employed.[6]

In 1859, 20 gold mines had been opened in the talc slates of Chesterfield and Lancaster counties, and 10 in the same slates in Abbeville and Edgefield, among the latter the celebrated Dorn mine from which more than a million dollars in gold has been taken. In Spartanburg, Union, and York counties there were 19 and in Pickens and Greenville 8 others.[5]

Gold mining, except in a few localities, remains practically as it stood in 1861. One notable exception, however, is found in the Haile gold mine, located in Lancaster county, which for many years has been perhaps the most consistent producer east of the Rocky mountains. The small silver production in 1902 was also from this mine.

Limestone occurs and to some extent has been quarried in York, Spartanburg, Laurens, and Pickens counties.[7] It is used for bridge work and in crushed form for road building.[8] However, owing to the abundance of granite for these purposes, it is used chiefly for burning into lime.

A few tons of manganese ore were mined near Greenwood in 1902, the mineral in great purity and abundance having been found at the old Dorn gold mine in Edgefield county and also in Abbeville, York, Laurens, and Anderson counties.[7]

Precious stones have been found at a number of places in the state. The first garnet found in the United States was picked up in Abbeville county, about 1825.[9] It was of a greenish yellow color. Garnets have also been found in Spartanburg county; rubies in Pickens; tourmaline in York, Edgefield, Laurens, Anderson, and Oconee; beryl in Edgefield and Laurens, and zircons in Abbeville and Anderson.

SOUTH DAKOTA.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells in the state of South Dakota for 1902.

TABLE 1.—*Summary: 1902.*

	Total.	Gold and silver.	Sandstones and quartzites.	Limestones and dolomites.	All other minerals.[1]
Number of mines, quarries, and wells	77	40	12	10	15
Number of operators	77	40	12	10	15
Salaried officials, clerks, etc.:					
Number	167	148	4	1	14
Salaries	$242,461	$222,590	$2,833	$1,278	$15,760
Wage-earners:					
Average number	3,131	2,914	94	55	68
Wages	$3,374,776	$3,217,456	$69,509	$43,714	$44,097
Contract work	$8,349				$8,349
Miscellaneous expenses	$264,452	$240,112	$4,669	$366	$19,305
Cost of supplies and materials	$1,992,575	$1,936,617	$9,703	$10,455	$35,800
Value of product	$6,769,104	$6,464,258	$110,789	$86,605	$107,452

[1] Includes operators as follows: Cement, 1; graphite, 2; gypsum, 2; lithium ore, 1; mica, 3; natural gas, 3 (6 wells); precious stones, 3 (no mines).

Within the Black Hills region, which covers about 3,500 square miles, and is embraced within Custer, Lawrence, Meade, Pennington, and Fall River counties, a great diversity of minerals is found. The gold and silver mines located here have since their discovery yielded many million dollars' worth of the two metals. This region also contains vast gypsum beds, used for plaster of Paris; mica, of which large sheets are exported; petroleum and natural gas; white, red, and variegated sandstones; white and purple limestones; granite; and marble.[1]

Both lode tin and stream tin are found in the Black Hills, the ore deposits covering an area of 500 square miles, and extending in a great semicircle of 40 miles, around and northwest of Harneys peak. The production of tin in this region, however, has not yet amounted to much, though great hopes are entertained of future development. Copper, iron, manganese, lead, tungsten, graphite, and spodumene are also found in greater or less quantities in the Hills.[2]

Near Sioux Falls, in Minnehaha county, are found inexhaustible deposits of the so-called jasper, in red, pink, cherry, purple, peachblow, and gray tints. This stone has been extensively used in building and for monuments.[2]

[1] King's Handbook of the United States, page 791.

The minerals of known occurrence in the state, but which were not produced in commercial quantities in 1902, are antimony, copper, fuller's earth, granite, iron, lead, marble, nickel, pumice, tin, tungsten, and uranium.[2]

In addition to the productive mines, quarries, and wells for which statistics are shown in Table 1, 114 operators reported gold and silver mines the work in connection with which was exclusively devoted to their care and development. During the year 1902 these operators employed 522 wage-earners and paid $581,163 in wages. The 99 salaried officers, clerks, etc., received $114,956. Miscellaneous expenses amounted to $45,210, and the cost of supplies and materials to $166,585.

Table 2 shows the value of the products of the manufacturing industries of South Dakota, based primarily on minerals mined and quarried, and also the value of all products manufactured in the state as reported to the census of 1900.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$12,231,239
Based upon products of mines or quarries:		
Clay, glass, and stone products	$293,568	
Iron and steel and their products	54,265	
Metals and metal products, other than iron and steel	2,351,342	
Miscellaneous industries	583,644	
		3,282,819
All other		8,948,420

The value of the manufactured products of the state, based primarily on minerals mined and quarried, was $3,282,819, or 26.8 per cent of the value of all the manufactured products. The total value of the product of the mines, quarries, and wells of South Dakota in 1902, plus the total value of all manufactured products in 1900, was $19,000,343, of which amount the product of mines, quarries, and wells for 1902 formed 35.6 per cent and that of manufactures for 1900, 64.4 per cent.

At the census of 1900 the manufacturing industries of South Dakota were reported as giving employment during the census year to an average number of 3,121 wage-earners and paying $1,544,409 in wages. The

[2] Ibid., pages 792 and 793.

operators of the mines, quarries, and wells of the state reported that they employed an average of 3,131 wage-earners during 1902, and paid $3,374,776 in wages. The combined industries, therefore, employed 6,252 wage-earners and paid $4,919,185 in wages. Mining gave employment to 50.1 per cent of the wage-earners, but paid 68.6 per cent of the wages, while manufactures gave employment to 49.9 per cent of the wage-earners and paid only 31.4 per cent of the wages.

Table 3, compiled from reports of the United States Geological Survey, shows the value of the annual production of the principal minerals of the state from 1890 to 1902.

TABLE 3.—*Value of annual production of the principal minerals: 1890 to 1902.*

[1] Estimates of the Director of the Mint; value of refined product; silver at coining value. The values given in Table 1 are the values at the mine.
[2] Includes production from North Dakota.
[3] Not reported separately.
[4] Commercial value.
[5] Census figures, except for gold and silver.

Gold.—The earliest authentic date of the finding of gold in the Black Hills is July 27, 1874, when small quantities of the precious metal were found in the bed of French creek, in Custer county, by miners accompanying the expedition of Gen. George A. Custer. From certain stories, still current, it would seem that some of the Sioux Indians and a few white men knew of the presence of gold in this region before 1874, but nothing definite is known concerning the actual facts.

A few weeks after the Custer expedition, other deposits of the precious metal were found, on December 23, 1874, about 3 miles below the present site of Custer, by a party entering the Black Hills region for settlement. Much prospecting was done in this vicinity during the winter, though little gold was found, and in the spring of 1875 the party was forced by the military to leave. The Black Hills country, then included within the Sioux reservation, was not open to settlement, and the Government made every effort to prevent prospectors from entering. This policy only intensified the desire to explore the region, and as a result of the widespread interest the Government, early in 1875, organized a special survey for the purpose of learning whether the mineral and other natural resources of the region warranted its purchase from the Indians.

The first authentic published statement of the finding of gold in the Black Hills was in a letter dated June 17, 1875, from the geologist in charge of the survey to the Commissioner of Indian Affairs at Washington, D. C., and which was first published in the Mining and Engineering Journal. The gold referred to in this letter was found June 12, 1875, in terraces or bars of quartz gravel, on the north bend of Castle creek. About a month later important discoveries in the placer deposits of Spring and Rapid creeks, northeast of Harneys peak, caused a rush in that direction, which was the first real stampede in connection with the gold excitement in the Black Hills. By this time several hundred prospectors had succeeded in gaining access to the region, and of this number more than a hundred staked out claims on Spring creek and commenced panning for gold.

The results of the survey having established the fact that the Black Hills region was of much greater value for mining purposes than it ever could be to the Indians, the Government finally purchased it from the Sioux for $4,500,000, and opened it for legal settlement February 28, 1877.

The discovery in the fall of 1875 of the rich placers of the Deadwood region, in Lawrence county, and, a few weeks later, of the rich conglomerate ores and of the great impregnated zone known as the Homestake Belt, indicated the permanent wealth of that part of the Hills and the tide of settlement turned accordingly northward from Custer. Since 1875 Lawrence county alone has far surpassed the balance of the region in the production of gold.

For ten years after gold was discovered the Black Hills had no railway facilities of any kind, but at the present time the northern part has excellent railway facilities, which fact has occasioned the opening up of many important mines. The central and southern hills are not so favored.

The gold bearing quartz veins are found chiefly in Pennington and Custer counties, in the central and southern part. Lawrence county, to the north, also has some valuable quartz veins. The ores of the impregnated zones are of great importance, one of them, the Homestake Belt, having furnished approximately three-fourths of the total output of gold in the Black Hills. The Homestake ore bearing area is an irregular belt 1½ miles long and one-half mile wide, near Lead city, forming perhaps the largest and most easily worked mass of low-grade gold ore in the world. In Lawrence county only have the ores of the impregnated zones been worked continuously for any length of time, though many claims, in Custer and Pennington counties, are said to carry as high values as the Homestake ore.

The cement ores within the Hills west and southwest of Deadwood were discovered in the early part of 1876, and in the same year the first quartz mill brought into the Hills reached Deadwood. The siliceous ores are

found only in the northern part, the producing ores lying in Lawrence county.

Placer gold is found in the gravel bars of all the streams and in the various terraces lining their valleys. The richest deposits, however, are either exhausted or can no longer be worked extensively with profit because of the lack of water supply. Associated with the gold in the placers are garnets, hematite and limonite pebbles, columbite, tantalite, cassiterite, and other less noticeable minerals.[1]

The following table, compiled from reports of the Director of the Mint, shows the annual production of gold in South Dakota from 1887 to 1902:

TABLE 4.—*Annual production of gold: 1887 to 1902.*

[Reports of the Director of the Mint.]

YEAR.	Fine ounces.[1]	YEAR.	Fine ounces.[1]
1887[2]	116,110	1895	187,187
1888[2]	125,775	1896	240,414
1889[2]	140,287	1897	275,491
1890[2]	154,800	1898	275,723

1893	193,809	1901	313,446
1894	159,594	1902	336,952

[1] Estimates of the Director of the Mint for refined product. The values given in Table 1 are the values at the mine.
[2] Includes production from North Dakota.

Silver.—Excepting the small but fairly regular amount of silver obtained from gold bullion, silver in the Black Hills is closely associated with lead.[2] Argentiferous galena ores are found in the Galena district southeast of Deadwood, in the Carbonate district northwest of Deadwood, and at Spokane. It is occasionally found elsewhere, but apparently little or no contribution to the output of the galena ores has been made from other than the three localities mentioned. The earliest developments worthy of note were made in 1881 at Galena.[3]

Silver-lead ores were found near Carbonate in 1886. Considerable lead and silver was produced by the Spokane mine during the years 1898–1900, but the mine is now idle. The character of the ore bodies in the various localities differs widely. They occur in the Algonkian in veins, in the Cambrian as shoots, and in the Carboniferous as contact deposits, the latter two graduating more or less into each other.[3]

Table 5, compiled from reports of the Director of the Mint, shows the annual production of silver from 1887 to 1902.

[1] Estimates of the Director of the Mint for refined product.
[2] Includes production from North Dakota.

Sandstones and quartzites.—One of the most promising stones of the West is the pink and red quartzite quarried near Sioux Falls, in Minnehaha county. The stone is so strong as to endure a pressure of 25,000 pounds to the square inch, is grained so closely as to be almost impervious to moisture, and will take a polish almost like glass, with which it favorably compares in durability. In color the stone varies from light pink to jasper red, and is one of the few stones now quarried in the United States which are adapted equally to rough building and both interior and exterior ornamental work.[4]

Eight of the 12 quarries in the state productive in 1902 were located in Minnehaha county, while Butte, Fall River, Hanson, and Lawrence counties had only 1 each. The entire output of these quarries in 1902 was valued at $110,789, an increase over 1901 of $93,142. The value of the sandstone produced for building purposes amounted to $42,162.

Limestones and dolomites.—The 10 quarries productive in 1902 were located in Custer, Lawrence, and Meade counties, and the output was valued at $86,605, of which $54,750 was for flux for blast furnaces.

All other minerals.—The single cement plant in South Dakota was built at Yankton, Yankton county, in 1889, and produced its first Portland cement in the following year, since which time it has been in successful operation. Chalkstone of the Colorado Cretaceous and the dark, fat overlying clay are the materials used.[5]

In many parts of the Hills graphitic slates abound, and in many places the percentage of graphite is sufficiently high to arouse some interest in the economic possibilities of the deposits. Considerable prospecting has been done in the central hills, particularly near Custer, Custer county, and Rochford, Pennington county.[6]

[4] Stones for Building and Decoration, by George P. Merrill, page 162.
[5] United States Geological Survey, "Mineral Resources of the United States," 1902, page 802.
[6] Mineral Wealth of the Black Hills, page 72.

The deposits of gypsum of the Black Hills are utilized for the manufacture of wall plaster at Spearfish, Lawrence county, and Hot Springs, Fall River county.[1]

Spodumene, a source of lithium salts, has recently acquired commercial importance in the Black Hills, and considerable local activity has been shown in the development of the industry. The deposits are all found in Custer and Pennington counties. This mineral first attracted attention during the tin mining activity in 1884, at which time its occurrence was noted in several localities.[2] The most noted of these is the Etta mine, which is the only locality in which this mineral was produced in 1902.[3]

The earliest explorations for mica in the Black Hills were made in 1879, the first property upon which much work was done being the McMacken mine, near Custer. Several other mines were opened somewhat later, but most of them practically ceased operating after 1884, the work during subsequent years until 1899 being merely sufficient development work to hold claims. The mineral is found in pegmatite dikes, which occur in great abundance in the granite region of Pennington and Custer counties.[4] Many of the dikes do not contain large mica books in sufficient quantity to make them profitable producers, but all have the mica present to a greater or less extent. In 1899 the output of mica was 20,299 pounds, valued at $18,000; in 1900 the sheet mica output reached the unprecedented amount of 65,000 pounds, valued at $45,000, while the production of scrap mica was 222 tons, worth $1,554.[5] In 1902 the production of rough mica amounted to 205 tons, valued at $17,250, and 6,000 pounds of sheet mica, worth $1,200.

The natural gas found in South Dakota is associated with flows of water at various localities in Hughes and Sully counties.[6] The first well in the state was drilled at Pierre, Hughes county, in 1892, and there is no apparent diminution of gas.[7] In 1902 the 6 productive wells had an output valued at $10,280.

The rose quartz reported under the head of precious stones was mined in Custer county, where there are immense quantities of the mineral in sight.[8]

TENNESSEE.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells in the state of Tennessee for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Phosphate rock.	Iron ore.	Marble.	Limestones and dolomites.	All other minerals.[1]
Number of mines, quarries, and wells	241	84	40	22	11	51	33
Number of operators	203	73	37	18	10	44	26
Salaried officials, clerks, etc.:							
Number	773	418	115	106	38	37	59
Salaries	$664,379	$381,939	$82,125	$71,535	$37,430	$27,826	$63,524
Wage-earners:							
Average number	10,890	6,220	1,597	1,299	607	698	469
Wages	$4,864,241	$3,213,532	$493,809	$512,702	$218,764	$222,475	$202,959
Contract work	$174,496	$14,094	$157,402				$3,000
Miscellaneous expenses	$720,483	$432,029	$81,882	$111,854	$11,268	$11,462	$71,988
Cost of supplies and materials	$850,485	$390,561	$93,715	$144,540	$18,725	$101,195	$101,749
Value of products	$9,533,782	$5,399,721	$1,308,872	$1,123,527	$518,256	$482,033	$701,373

[1] Includes operators as follows: Barytes, 6; clay, 9; copper ore, 2; fluorspar, 1; gold and silver, 2; mineral pigments, crude, 1; natural gas, 1; petroleum, 1; and sandstones and quartzites, 3.

Tennessee has long been conspicuous as a mining state; for more than one hundred years its great wealth of iron ore deposits has engaged the attention of miners. The coal fields, comprising almost one-eighth of the total area of the state, are practically inexhaustible and have been worked extensively. Since the discovery of phosphate rock early in the present decade its mining has grown until the state's output of this mineral has become second only to its production of coal. The marble deposits of the state have long been famous. Their early development brought the state into prominence, and with the increasing demand for "Tennessee" marble the industry of its quarrying has grown steadily. Another important branch of mining industry is that which has developed around the valuable and extensive deposits of copper ore in the Ducktown district.

Manganese is of frequent occurrence in various parts of the state, chiefly in the eastern section in association with the iron ores. The first manganese ore mined in the United States was produced near Whitfield, Hickman county. The mine was first worked in 1837, and the output was used for coloring earthenware. The two sections from which manganese ores have been taken in commercial quantities are the vicinity of Sweetwater, Monroe county and in Unicoi county.[1]

Lead and zinc ores occur at numerous points in the eastern and middle parts of Tennessee, and a half century or more ago in the Valley range west of the line of Red Knobs lead mining gained considerable headway. The industry has not been revived, although deposits of galena occur that seemingly would warrant commercial exploitation. Interesting features of this locality are the old and quite extensive "diggins," about which the oldest inhabitants and the Indians before them knew nothing.[2] It has been surmised that these excavations were made in a search for galena. Whether the object was to secure galena or other minerals, these workings point unerringly to an era of mining activity which antedates both history and tradition, and most probably was cotemporaneous with the still more extensive and systematic operations in the mountains of North Carolina, and with prehistoric copper mining in the Lake Superior region. The deposits of zinc ore, especially those in the vicinity of Knoxville, have been worked in a desultory way for many years, and considerable quantities of ore have been calcined and shipped to eastern smelters.[3]

Millstones of excellent quality have been made from some of the rock formations. Those made from chert were in great demand at one time and were regarded as being equal to the French buhrstone.[4]

Cement has been manufactured at numerous points from the outcroppings of the limestone, and asphaltum, granite, gypsum, and roofing slate are known to occur in greater or less quantities.

[1] United States Geological Survey, Sixteenth Annual Report, 1894–95, Part III, pages 423 and 424.

[2] Geology of Tennessee, by James M. Safford, A. M., Ph. D., pages 484 and 485.

[3] United States Geological Survey, "Mineral Resources of the United States," 1882, page 367 ff.

[4] Geology of Tennessee, page 511.

The following minerals are known to occur in the state, but were not produced in commercial quantities in 1902: Asphaltum, cement, granite, gypsum, lead ore, manganese ore, millstones, slate, and zinc ore.

A total of $22,940 was expended in the state in development work during 1902, but no product was realized. The minerals receiving attention in this way were natural gas, petroleum, and copper ore.

Table 2 shows the relative importance of the manufacturing industries closely allied to or based upon the mining industry, using as their raw material the products of mines and quarries.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$108,144,565
Based upon products of mines or quarries:		
Chemicals and allied products	$1,649,078	
Clay, glass, and stone products	2,056,386	
Iron and steel and their products	9,848,440	
Metals and metal products, other than iron and steel	1,308,700	
Miscellaneous industries	3,703,078	
		18,565,682
All other		89,578,883

The total value of the products of the manufacturing industries based on mining was $18,565,682 or 17.2 per cent of the total value of the product of all manufacturing industries in 1900. During the same year there were employed in all branches of manufactures 50,504 wage-earners, who were paid $16,647,638 in wages. In 1902 the mines and quarries gave employment to 10,890 wage-earners, who received $4,864,241 in wages. By combining the figures of these two branches of industry it is disclosed that 82.3 per cent of the wage-earners receiving 77.4 per cent of the wages were employed in manufacturing, while 17.7 per cent of the wage-earners receiving 22.6 per cent of the wages were employed in mining.

The following table shows the value of the annual production of the principal minerals of the state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Phosphate rock.	Iron ore.	Marble.	Limestones and dolomites.
1890	$2,395,746	[1]	[2]	$419,467	$73,028
1891	2,668,138	[1]	[2]	400,000	70,000
1892	2,355,441	[1]	$505,359	350,000	20,000
1893	2,048,449	[1]	392,771	150,000	126,089
1894	2,119,481	$67,158	288,005	231,796	188,664
1895	2,349,032	82,160	447,852	362,277	156,898
1896	2,281,295	57,370	432,932	381,373	157,176
1897	2,329 534	193,115	479,485	441,954	113,774
1898	2,337,512	498,392	481,192	316,814	182,402

[1] No production.
[2] Value not reported.
[3] Includes production from North Carolina.
[4] Census figures.

Coal, bituminous.—The most valuable contribution to the mineral wealth of the state are the coal fields, comprising more than 5,000 square miles and traversing the state in a northeast and southwest direction.[1] The belt in which these coal measures occur is coextensive with the Cumberland table-land and varies in width from 71 miles at the northern boundary to 50 miles at the Georgia and Alabama state line.[2] In this belt the industry of coal mining has been developing since long before the Civil War, during which its growth was temporarily interrupted.[1] Practically all the mining of these earlier years was on a petty scale, and outside of Nashville and Memphis very little coal was used, except for blacksmithing purposes.[3] The industry did not reach a scale of any considerable importance until some fifteen years after the war,[3] but it has developed steadily since. In 1892 its progress was seriously interfered with by strikes. Since 1893 production has increased rapidly, the output for 1902 being 50 per cent greater than that for 1897, and more than double the production at the beginning of the decade.[4] Nineteen counties of the state are embraced wholly or in part within the coal belt, and the range of the industry has expanded until coal is produced in practically all of these counties. In Campbell county is a part of the famous Jellico steam-coal field. The Sewanee vein, one of the most important, is extensively worked in Grundy county. Much high-grade coke is made from this product.

Other counties in which extensive coking establishments are under way are Claiborne, Hamilton, Marion, Rhea, and Roane.[5] Eighty-eight per cent of the yield in 1902 was from the following counties: Anderson, Campbell, Claiborne, Cumberland, Grundy, Marion, Morgan, Rhea, and Scott. The annual production of the Tennessee mines from 1870 to 1902 is shown in Table 4.

Phosphate rock.—The phosphate rock mined in this state has been classified into three groups or varieties, according to color. These are blue rock, which occurs mainly in Hickman county; white rock, as typified by the deposits occurring in Perry county; and brown rock, deposits of which are confined principally to Maury county.[1] Rocks containing varying percentages of phosphate occur in several other counties in the phosphate rock region, which extends from the vicinity of Nashville, south to the Tennessee river.

The discovery and exploitation of the deposits of this valuable mineral in the state constitutes, in the main, a repetition of the events attending the discovery of phosphatic rock in both South Carolina and Florida. In all these cases the valuable phosphatic contents of the rock became known by accident. The existence of the rocks was a matter of common knowledge, and their peculiarities, at least in the case of South Carolina and Tennessee, had been the subject of extended study and investigation by geologists. A remarkably accurate description of the physical characteristics of the phosphate deposits of Tennessee was given by Doctor Safford, in 1869, in his Geology of Tennessee. Their chemical nature and great commercial value, however, remained a secret for a quarter of a century longer.

Certain kinds of phosphate rock in Tennessee have been used for many years in building operations requiring stone. An object of interest to visitors to the fields at present is a stone house made almost entirely of phosphate rock many years ago by a religious recluse.[2]

The discovery of the deposits, the development of which marked the beginning of phosphate mining in the state, occurred in October, 1893. During that year Messrs. L. Bates and R. Childs had been prospecting for coal in this section and a Mr. Harder, while fishing in Swan creek in Lewis county, found some peculiar looking rocks, which he sent to these coal prospectors for examination. Thinking the rocks indicated coal these prospectors shipped them to Prof. J. C. Wharton, an analytical chemist of Nashville. Upon examining them the chemist found one of the specimens to be a high grade of phosphate rock.[2] When the discovery became known the scenes enacted in South Carolina and Florida were repeated. Prospectors and speculators were early on the ground, and other discoveries quickly followed in all directions. By July, 1894,[3] several companies had been organized, extensive tracts of land had been purchased or leased, and the industry of phosphate mining was well under way. In the latter part of this year the phosphate rock of Tennessee first became a distinct factor in the market. About 45,000 tons were mined and shipped between July, 1894, and July, 1895. For two years after the beginning of the industry all the phosphate rock that left the state was mined in Hickman county.[4] In December, 1895, the Hon. S. Q. Weatherby, while passing along a road near Mt. Pleasant, in Maury county, observed in the deep cuts a thinly laminated rock that to him suggested zinc ore. Actuated mainly by curiosity, and with no thought of making any valuable discovery, he broke a piece to study its structure, and found that instead of confirming his impression as to zinc ore it presented a granulated appearance characteristic of the phosphate rock of Lewis and Hickman counties. Samples were secured and sent to Mr. Lucius P. Brown, an analytical chemist of Nashville, for examination, and they were found to contain phosphate of lime ranging in percentages from 75.2 to 78.1. For some months this new discovery was not allowed to become known beyond a chosen few, and in the meantime options were taken on much of the land containing the phosphates. Mining operations were begun within the town limits of Mt. Pleasant in July, 1896, and the first shipment was made on the 20th of that month. On this public disclosure there was excitement in all the surrounding neighborhood, pervading all classes.[5] The industry was prosecuted on a commercial scale from the start, and grew rapidly. Table 5 shows the monthly shipments of rock from Mt. Pleasant during the first thirteen months.

TABLE 5.—*Monthly shipments of phosphate rock from Mt. Pleasant district: 1896 and 1897.*

[United States Geological Survey, "Mineral Resources of the United States."]

DATE.	Pounds.	DATE.	Pounds.
1896.		1897.	
July (11 days)	784,797	January	16,518,412
August	5,783,943	February	15,244,650
September	5,746,782	March	15,061,300
October	5,016,589	April	18,514,460
November	10,772,986	May	22,323,520
December	15,302,292	June	12,369,000
		July	20,142,900

By the latter part of 1896 the center of activity had moved from Hickman to Maury county, and it has remained there since. In 1898 Tennessee contributed 22 per cent of the total production of phosphate in the United States, and 12.4 per cent of the aggregate output of the world.[6] In 1899 the state exceeded South Carolina in production, and has been second to Florida since.

The outlook for the industry in the state is promising. Conditions are favorable for the economical operation of fertilizer factories. The shales with which the deposits of phosphate are interstratified are rich in sulphur, from which can be manufactured the sulphuric acid necessary in the treatment of phosphate rock. Thus the two essential raw materials in the manu-

1898	308,107		

Iron ore.—The iron ore deposits of Tennessee are comprised within four clearly defined belts extending across the state. The central, or Cumberland, belt embraces an area of about 5,000 square miles,[2] and is coextensive with the coal fields. The ore found in this belt is red hematite. In a relative sense this belt is of minor importance.[3] The other three belts are producers, and the bulk of the state's great wealth in iron ores lies within their limits. The eastern belt extends along the Smoky mountains. Limonite, hematite, and magnetic ores are found in this region. They do not occur in regularly stratified beds nor in true veins, but in masses of varying sizes, ranging from small lumps to blocks of 10 and 15 feet in diameter. Ore recently discovered in this district is highly impregnated with magnetic properties, and exerts a marked influence over the needle of a compass 10 feet away. There are indications that this ore exists in large quantities.[4] The Dyestone belt is parallel with the base of the Cumberland table-land.[5] The chief ore of this belt is a stratified red iron rock of highly fossiliferous character. The belt is remarkable for the extent and richness of its ore deposits, from which has been taken the bulk of the state's production. The ore averages 60 per cent metallic iron.[4] The western belt traverses the state from north to south along the dividing line between middle and west Tennessee. It is 50 miles in width, and embraces an area of more than 5,000 square miles. The ore throughout this belt averages about one-third metallic iron.[5]

The iron ores of Tennessee have long been celebrated. The first settlers in the state began the manufacture of iron soon after the close of the War of the Revolution.[6] Three-quarters of a century ago iron in the form of blooms was manufactured and shipped to Pittsburg.[7] In 1850 Tennessee stood fourth among the states in the production of iron ore,[8] and except during the Civil War the industry has grown steadily since that time. In the manufacture of car wheels and the best grades of bar iron no ore is superior to the ore of Tennessee.[9] In Table 7 is shown the annual production of iron ore in the state from 1890 to 1902.

TABLE 7.—*Annual production of iron ore: 1890 to 1902.*

Marble.—The marbles of Tennessee, forming one of the state's principal mineral resources, are widely distributed. They have been quarried in the eastern, middle, and western sections of the state.[10] The chief deposits, however, are comprised within an almost unbroken zone or belt 20 miles in width and more than 100 miles in length, situated in eastern Tennessee, with Knox county as its center.[11] Within this range the supply of marble is practically inexhaustible. There are many kinds suitable for the various uses to which marble has been put. In color almost every tint and shade between white and black is found in a great variety of combination. There is no record of the earliest marble working in the state except that chiseled into the first products of the industry. These old tombstones, still sharp and clear in outline, scattered through the churchyards of the region, and especially those around the First Presbyterian church in Knoxville, serve the double purpose of carrying the date of their manufacture back into the morning of the nineteenth century and of affording the most convincing proof of the enduring qualities of the marble from which they were cut. Marble quarrying along systematic lines dates from April, 1838, the first quarry being opened at Rogersville, the seat of Hawkins county.[12] Orville Rice, a Yankee clock peddler,[13] was elected president, and the company was organized for the purpose of sawing marble and establishing a marble factory in the vicinity of Rogersville.[14] This quarry was located on the line of the stage road, and

soon after the quarrying operations were started Mr. Rice began the erection of a large brick tavern, the interior of which he richly and profusely ornamented with marble mantels, shelves, steps, and wainscoting. The house was known as "Marble Hall," and is still standing, being used at present as a residence.[1] A block of the light mottled strawberry variety was sent to the builders of the Washington Monument; it was inscribed "Hawkins County Block." Another block, sent by authority of the legislature, was called the "Tennessee State Block."[1] These attracted the attention of the building committee of the Capitol at Washington, D. C., and although they had specimens from all the then known marble deposits of the country, they decided in favor of the East Tennessee marble.[2]

Following this decision an extensive quarry was opened by the Government at a point near Rogersville where the Holston river intersects the marble range, and from here many thousand cubic feet were taken. It was used in constructing the balustrades and columns of the stairs leading up to the House and Senate galleries, the walls of the marble room, and other parts of the building. About one-half of the ornamental material in the Capitol is of Tennessee marble.[3] This unequaled means of advertising at once brought the state into national prominence as a marble producer. In 1902 Tennessee ranked second in the production of marble for interior decoration and fourth in the total value of marble products.

Limestones and dolomites.—Most of the product of the limestone and dolomite quarries is burned into lime or is used as flux in iron furnaces. The building limestones of the state have only a local reputation, are generally not of high grade, and are quarried to only a limited extent. Almost one-half of the output of building stone of this character during 1902 was from Davidson county. A compact, finely fossiliferous, light pink spotted limestone occurs near Nashville. Near Chattanooga a magnesian limestone of bluish black color is quarried for local use. This stone is said to be durable. Other localities where limestones occur and have been quarried to some extent for building purposes are near Columbia, and at Carters Creek, in Maury county, and at Morristown and Springfield. A fine grained, compact, and light colored oolitic stone, which cuts to a sharp, smooth edge and seems to be a most excellent stone, occurs near Sherwood station.[4]

All other minerals.—Barytes occurs in numerous places in the state. Since it is frequently the matrix of lead ore, its occurrence is notable in the lead regions. There are important deposits in Greene county and at Haysboro, in the vicinity of Nashville.[5]

Except in the use of common clay for brick, very little mining of this mineral is carried on. A large bed of what is claimed to be kaolin or porcelain clay occurs in the state,[6] but there was no production from it in 1902. The production of clay in 1902 consisted of pipe, ball, fire, and stoneware clay, and was mined to some extent in Carroll and Hardeman counties, but chiefly in Henry county.

While deposits of copper ore occur at numerous places in the mountain region, the great deposits are in the Ducktown district of Polk county, in the extreme southeastern portion of the state. These ore deposits are not true fissure veins; they are great lenticular masses of ore and gangue material lying conformably between strata of country rock. These masses or veins occur generally in long ranges or belts, one succeeding another longitudinally in approximately the same line, and their feather edges not infrequently overlap though thrown apart by intervening rock.[7] The discovery of copper in Polk county followed the discovery of gold made some years previously on Coqua creek. It was in the search for the latter metal that one of the gold hunters, Mr. Semmons, in 1843, found crystals of red copper ore while panning the gravels for gold in a branch at a point where the Hiwassee copper mine was later opened. Further investigation was carried on by a Mr. Grout and several rich specimens of native copper were found. In 1847 a German miner named Weber secured possession of the property and made the first shipment of copper ore from the district. This consisted of 90 casks and was sent to the Revere Smelting Works, near Boston. Before he had learned the real value of his shipment the miner left and operations ceased. In 1849 Mr. John Caldwell reached the district in a search for copper ore, and to him, perhaps, more than to any other is due the credit for the development and exploitation of these valuable and extensive deposits. The first mine opened in the district was the Hiwassee in August, 1850. Next came the Cocheco in October of the same year, and one year later the Tennessee. In 1852 two other mines were opened. In 1853 this number was increased by 6 others with 3 more in 1854. When the almost insuperable obstacles in the way of the transportation of machinery through the wild mountainous country to the district and the hauling of the product from it are considered, this rapid development is all the more remarkable and indicates plainly the richness and extent of the deposits. By the end of September of the following year, 1855, 14,291 tons of ore, worth more than a million dollars, had been shipped from the district. The Ducktown district continued to develop; to the industry of mining was added that of smelting, and later rolling mills were constructed. Mining operations were interrupted during the greater part of

the Civil War period. As a result of this prolonged suspension the mining properties suffered greatly, skilled laborers were dispersed, and, on the whole, conditions in 1865 were altogether unfavorable for a resumption of activity. However, the excellent quality of the Ducktown copper, and the demand for it, furnished a very potent stimulus, and soon operations were under way on an even wider scale than before. The copper industry was one of the first to recover from the effects of this period of great industrial depression, and has continued to be an important factor in the state's mineral development since.[1]

Fluorspar occurs in numerous places in the state and especially in Smith, Trousdale, and Wilson counties. Some of the deposits are of commercial importance. Fluorspar mining is new in the state, being a development of the last one or two years.[2]

The only section of the state in which gold has been found in any important quantity is the southeastern part between the French Broad river and the Georgia line. Most of the mining operations have been confined to Coqua creek and vicinity, a strip of country about 10 miles long by 2 or 3 miles wide. The first discovery of gold in the state occurred in this region in 1831. Considerable placer mining was done at this time and some gold has been mined each year since, but the industry is of minor importance.[3]

The only production of crude mineral pigments reported for 1902 was a small quantity from James county.

The beginning of the production of natural gas in the state is of quite recent date, and the only report in 1902 was of a small amount in Franklin county.

The first successful borings for petroleum in the state were probably those in the southern part of Overton county in 1866.[4] The industry at present is of minor importance, the total production reported in 1902 being a small quantity from Fentress county.

The workable sandstones of the state are not widely distributed. A fine grained light pink and coarse buff variety occurs at Sewanee and a coarse gray variety at Parksville.[5]

TEXAS.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells in the state of Texas for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Petroleum.	Coal, bituminous.	Quicksilver.	Limestones and dolomites.	Sandstones and quartzites.	Siliceous crystalline rocks.	Natural gas.	All other minerals.[1]
Number of mines, quarries, and wells	1,067	955	26	5	35	13	8	14	11
Number of operators	308	211	24	3	34	13	8	5	10
Salaried officials, clerks, etc.:									
Number	1,210	999	91	19	30	11	8	1	51
Salaries	$664,802	$444,129	$90,086	$19,876	$21,393	$8,689	$8,400	$2,000	$70,229
Wage-earners:									
Average number	3,853	723	1,979	233	275	191	56	.....	396
Wages	$2,261,639	$699,209	$991,391	$87,414	$124,272	$100,399	$41,184	.....	$217,770
Contract work	$1,387,796	$1,363,463	$38	$235	.....	.....	.....	$18,812	$5,248
Miscellaneous expenses	$923,769	$713,176	$102,237	$6,305	$8,458	$7,644	$2,304	$2,612	$81,033
Cost of supplies and materials	$1,051,457	$675,937	$99,127	$73,373	$34,222	$21,261	$6,095	$125	$142,317
Value of product	$6,981,532	$4,174,731	$1,477,245	$254,350	$228,662	$165,565	$60,003	$14,953	$606,023

[1] Includes operators as follows: Asphaltum and bituminous rock, 1; cement, 2; clay, 3; gold and silver, 1; gypsum, 2; iron ore, 1 (2 mines).

As shown in the above table, the total output of the mineral industry in Texas during 1902 was valued at $6,981,532; of this amount the product of petroleum wells, valued at $4,174,731, formed 59.8 per cent, and that of coal mining, with a valuation of $1,477,245, constituted 21.2 per cent. Petroleum and bituminous coal together represented more than four-fifths of the total value of the mineral production in the state.

The gypsum reported in Texas was about one-tenth that of the entire United States production and ranked third in importance among the minerals of the state. There were but two establishments reporting, and therefore the separate statistics for this industry are not published.

Quicksilver ranked fourth in value among the minerals of the state, the value of the production amounting to 16.4 per cent of the total for the United States. Following in the order of their importance may be mentioned the production of cement, limestones and dolomites, sandstones and quartzites, gold and silver, siliceous crystalline rocks, natural gas, iron ore, clay, and asphaltum and bituminous rocks.

A large number of minerals, for which no commercial production was reported during 1900, are known to occur in Texas. Among these may be mentioned the following: Antimony, asbestos, bismuth, copper, feldspar, garnet, manganese, marble, molybdenum, slate, and talc. Agate, amethyst, opal, and tourmaline have also been found in the state.

Development work was carried on during the year at 71 mines, quarries, and wells by 51 operators, their attention being almost entirely directed to petroleum and gas wells, coal mines, and sulphur and pyrite mines. These operators paid $37,209 to their 36 salaried officials, clerks, etc. They also gave employment to 48 wage-earners and paid $46,766 in wages. The amount expended for contract work was $245,542; the miscellaneous expenses were $29,912; and the cost of supplies and materials was $51,679.

The relative importance of manufacturing industries closely allied to or based upon the mineral industry, and using as their raw material the products of the mines and quarries, is shown in Table 2 by value of products.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.		Value of product.
All manufactures		$119,414,982
Based upon products of mines or quarries:		
Chemicals and allied products	$637,827	
Clay, glass, and stone products	2,490,360	
Iron and steel and their products	2,949,000	
Metals and metal products, other than iron and steel	8,346,672	
Miscellaneous industries	5,199,974	
		19,623,833
All other		99,791,149

Table 2 shows that the value of the manufactured products bearing intimate relation to the mining industry amounted to $19,623,833, or 16.4 per cent of the

total manufactured product of the state in the year 1900. During this year there were employed in the manufacturing industries in Texas 48,153 wage-earners, who received $20,552,355 in wages. In 1902 the operators of the productive mines, quarries, and wells of the state reported the employment of 3,853 wage-earners, to whom was paid the sum of $2,261,639. Of the combined figures it is shown that 92.6 per cent of the total wage-earners were employed by manufacturing establishments in 1900 and that they received 90.1 per cent of the wages, while but 7.4 per cent of the entire number of wage-earners were, in 1902, engaged in the mineral industry, and were paid 9.9 per cent of the total wages.

The following table compiled from the reports of the United States Geological Survey, shows the value of the principal minerals produced in Texas from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Petroleum.	Coal, bituminous.	Limestones and dolomites.	Sandstones and quartzites.	Siliceous crystalline rocks.
1890	$227	$465,900	$217,835	$14,651	$22,550
1891	227	412,300	175,000	6,000	75,000
1892	225	569,333	180,000	48,000	50,000
1893	210	688,407	28,100	77,675	38,991
1894	300	976,458	41,526	62,350	(1)
1895	250	913,138	62,526	97,336	(1)
1896	1,050	896,251	77,252	36,000	(1)
1897	37,662	972,323	57,258	30,030	3,500
1898	277,135	1,139,763	70,321	77,190	4,685
1899	473,443	1,334,895	100,025	35,738	84,945
1900	871,996	1,581,914	124,728	37,038	76,069
1901	1,247,351	1,907,024	209,658	111,568	27,005
1902[2]	4,174,731	1,477,245	228,662	165,565	60,003

[1] Not reported separately.
[2] Census figures.

Petroleum.—The presence of oil in tar springs, oil seeps, etc., in Texas had been known for many years, but the first record of the discovery of petroleum in quantities sufficient for use seems to have been about 1867, when it was found at a point 15 miles southeast of Nacogdoches.[1] But little attention was paid to these petroleum deposits until 1883. During the period from 1887 to 1890, 90 wells were drilled in the vicinity of Nacogdoches. Statistics of production first appeared in 1889, when 48 barrels were reported, with a valuation of $340.

About 1894 oil was accidentally found at Corsicana, during the sinking of an artesian well.[2] A company was formed and other wells were sunk, oil being discovered in 1898 at a depth of 1,040 feet. The drilling in this locality is entirely through a hard clay, and the oil obtained, resembling the Kansas product, is better than the Ohio oil, but not as good as the Pennsylvania. The Corsicana product has been used exclusively for fuel and in the manufacture of illuminating gas in Dallas, Houston, and Austin.[3]

[1] Bulletin of the University of Texas, No. 5, July, 1901, pages 1 and 2.
[2] United States Geological Survey, Nineteenth Annual Report, 1897, Part VI, page 104.
[3] The Mineral Industry, 1897, Vol. VI, page 515.

The unexpected outburst of a 6-inch gusher in 1901 near Beaumont, in Jefferson county, was the sensation of the petroleum industry in the United States. Beginning on January 10, in nine days a stream 160 feet in height emptied out an estimated quantity of 500,000 barrels of oil before being capped. As a result of this wonderful find many companies were formed, drilling commenced without delay, and in less than six months there were 211 operators in that county. The elevation known as Spindle Top embraces about 125 acres, and is in its highest part 40 feet above sea level; the surrounding plain slopes southward 18 miles to the Gulf of Mexico. This was the scene of most active operations, and land was divided into small lots selling for fabulous prices.[4]

At Sour Lake, in Hardin county, a slight development was reported in 1893, but it was not until 1901 that any considerable results were obtained. A gushing well, flowing an 8-inch stream, was drilled early in 1902, and during the year a number of wells have been completed and the value of the field has been fully established.

At the Saratoga well, 12 miles northwest of Sour Lake, successful development work in 1902 was reported. In Bexar county a small quantity of heavy oil was produced and supplied a local demand. Work in the Nacogdoches district, in which there were the first indications of petroleum in the state, has been practically abandoned, and no production was reported for 1902.[5]

Table 4, compiled from the reports of the United States Geological Survey, presents the annual production of petroleum in the state of Texas from the beginning of the industry to the present time.

TABLE 4.—*Annual production of petroleum: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Barrels.	YEAR.	Barrels.
1889	48	1896	1,450
1890	54	1897	65,975
1891	54	1898	546,070
1892	45	1899	669,013
1893	50	1900	836,039
1894	60	1901	4,393,658
1895	50	1902	18,083,658

This table indicates the wonderful development of the Texas petroleum fields since 1900. During 1902 the volume of production was second only to that of Ohio. In a number of counties, not actual producers, petroleum has been located in greater or less quantity. Development work has been carried on to a very great extent, over $400,000 having been expended during 1902 in nonproductive operations in connection with the petroleum industry.

Coal, bituminous.—Coal was known to exist in Texas as early as 1836, and in 1840 a company was incorporated

[4] United States Geological Survey, "Mineral Resources of the United States," 1901, pages 565 to 567.
[5] Ibid., 1902, pages 571 and 572.

to mine this fuel. A further investigation in 1846 of the Trinity river district, 200 miles above Galveston, resulted in the finding of coal in more extensive measures than was anticipated, both anthracite and a semibituminous coal resembling cannel coal, being discovered.[1] In 1859 the first geological report of Texas contained an estimate as to the area of the coal fields in the state, and in 1866 the coal seams at Belknap were mentioned as well as a bed of coal about 6 miles north of that place.[2]

Coal production in Texas during 1902 may be said to have centered in Erath county, where the amount reported exceeded that of all the other counties in the state. Webb county, in the southern part of the state, was second in importance, and Wise county in the northern part of the state, ranked third. Maverick county, on the Rio Grande river, and adjoining Webb county, was fourth, and Parker county, between Erath and Wise counties, ranked fifth, and a small production was also reported in Eastland county. These were all bituminous localities, and their total production was valued at over $1,300,000 during 1902.

The secondary coal fields of Texas, for which production of lignite was reported during 1902, were found principally in the following counties, ranking in the order named: Milam, Bastrop, Medina, Robertson, and Wood. Several other minor productive localities were reported.

Coal measures are found in Texas in three districts. The northern or bituminous field is the southern extremity of the Western coal basin of the United States; the semibituminous seam along the Rio Grande is second in importance; and larger than either in extent and thickness, but least in value of production, is the lignite field, lying in the central part of the state, and including over fifty counties in whole or in part.[3]

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of coal in Texas from 1883 to 1902:

TABLE 5.—*Annual production of coal, bituminous: 1883 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.	YEAR.	Short tons.
1883	100,000	1890	184,440	1897	639,341
1884	100,000	1891	172,100	1898	686,734
1885	133,928	1892	245,690	1899	883,832
1886	100,000	1893	302,206	1900	968,373
1887	75,000	1894	420,848	1901	1,107,953
1888	90,000	1895	484,959	1902	901,912
1889	128,216	1896	544,015		

As shown in the above table there was a uniformly increasing production of coal in Texas from 1891, until within the last year, when the vast exploitation of petroleum wells exerted a depressing effect on the industry. The reports for 1902 showed a decrease in production of 206,041 short tons, with a valuation of $429,779 less than that reported for the previous year.

Quicksilver.—The existence of cinnabar, in the neighborhood of California Hill, was known to the Comanche Indians, as evidenced by the use in rude paintings and hieroglyphics found on the limestone bluffs in this locality of a vermilion pigment prepared from this ore. With this exception no knowledge of these cinnabar deposits reached civilization until about 1887, when rumors of their existence were reported, but it was not until 1894 that their location was actually discovered. During 1896 and 1897 considerable prospecting was done, and in 1900 the first furnace was erected and ore treatment was begun.[4]

The cinnabar deposits occur in massive limestone, in siliceous shales, and in a white, earthy, clay-like rock; the ore is generally soft and friable, differing in this respect from the cinnabar of the New Almaden mine in California, which is found in hard masses or in veinlets.[5] The mercury occurs, not only as cinnabar and as yellow sulphide, but it also is present in the native state in several localities. Cinnabar, however, is the principal mineral.

The mining operations have been most crude in method; often the material mined has been carried to the surface on the backs of the Mexican miners. A scarcity of water and fuel has delayed the complete development of these quicksilver deposits, but the recent discovery of asphaltum and coal and the possible occurrence of petroleum may increase the general interest in this locality.

During 1900 the first production of quicksilver in Texas was reported, amounting to 750 flasks; in 1901 this amount was increased to 2,932 flasks, valued at $132,438, while in 1902 there were reported 5,319 flasks of quicksilver and 1,300 short tons of unrefined cinnabar, with a total valuation of $254,350. This production is entirely in Brewster county in the vicinity of Terlingua.

Limestones and dolomites.—Valuable limestone deposits are scattered throughout a large portion of the state; a production was reported in 25 counties during 1902. The principal productive locality is in the vicinity of Austin, Travis county, where a light colored, fine grained limestone is quarried. El Paso county is second in value of product and Williamson county, adjoining Travis on the north, is third. Much of the production is a compact, fine grained cretaceous stone of excellent quality, a part of which is crystalline, and when highly polished is suitable for interior decorative work. A dark mottled variety of stone also occurs in some parts of the state.[6]

[5] Transactions of the American Institute of Mining Engineers, Vol. XXV, pages 72 and 73.
[6] Stones for Building and Decoration, by George P. Merrill, page 322.

There was quarried in Texas during 1902 limestone and dolomites to the value of $228,662.

Sandstones and quartzites.—The principal sandstone quarrying operations in Texas during 1902 were in Brazos county, where a carboniferous stone of a gray color is obtained.[1] Ward county, in the extreme western part of the state, was the second locality in importance, with Burnet and Fayette counties, respectively, third and fourth in rank.

Before 1901 the sandstone quarrying in Texas was of but little consequence, but during that year and 1902 the industry grew until it has taken an important place among the minerals of the state. The production of 1902 was valued at $165,565.

Siliceous crystalline rocks.—The siliceous crystalline rocks quarried in the state during 1902 were obtained in Llano and Burnet counties, in the central part of the state, near the towns of Llano, Kingsland, and Burnet. Both fine and coarse red granite were quarried, the latter corresponding closely to that obtained from Platte canyon, Colorado. Red and gray granites occur in Gillespie county, although no production was reported from that locality during the year.[2]

The value of siliceous crystalline rocks quarried in Texas in 1902 was reported as $60,003, and about three-fourths of this stone was used for monumental purposes. The remainder, amounting in value to $13,784, was used in building operations.

Natural gas.—While prospecting for oil and gas in the southwestern part of Washington county during 1879 a well was drilled which gave a strong flow of natural gas at a depth of about 160 feet. No practical use was made of this gas, and the first commercially successful well in this locality was not drilled until 1888.[3]

The production during 1902 was all obtained in Jefferson and Navarro counties, in the Beaumont and Corsicana oil districts. The value of the output reported by the 14 wells in operation during this year was $14,953, indicating a decrease in comparison with 1900 and 1901.

In some instances the gas obtained was used to force the flow of oil wells. It spread over the surface of the petroleum in the porous limestone, and thereby started the wells into operation.

All other minerals.—The principal mineral in Texas for which statistics may not be separately reported is gypsum, and its production ranks next to that of bituminous coal. Hardeman county was the only locality where gypsum or gypsite was quarried, and the product was sold chiefly as cement or wall plaster, although a small amount was reported as consumed in making plaster of Paris.

Cement also is quarried to a considerable extent in Dallas and Bexar counties, and in value of production ranks among the important mineral products of the state.

Silver bearing quartz is mined quite extensively in Presidio county, in the locality of the Rio Grande. Blanket deposits in limestone are found in pockets and in some places in the strata. The ore is transported in wagons to the town of Shafter, where it is reduced to the metallic state by amalgamation.

Small quantities of stoneware and fire clay were mined by individuals near Elmendorf, in Bexar county. The stoneware clay was not prepared at the mines, but was sold in the raw state to a pottery establishment.

Deposits of asphaltum and asphaltic rock exist in Texas, but the only production during 1902 was a small amount of liquid asphaltum obtained from test holes sunk by an oil and development company in Travis county.

Iron ores are found in a number of counties in Texas, and some of the product is of Bessemer quality. In character, the deposits are a brown hematite or bog ore, and the occurrences are found in a continuous and persistent ledge covering the mountains of the eastern part of the state.[4] According to the first record the iron industry in Texas was started in Cass county, where a blast furnace was in operation for some years prior to 1859. A number of other furnaces and bloomeries were also reported about this time, those in Cherokee county, near Rusk, having been established during the Civil War.[5]

UTAH.

Table 1 is a summary of the statistics of the productive mines and quarries in the state of Utah for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Gold and silver.	Coal, bituminous.	Copper ore.	Limestones and dolomites.	Sandstones and quartzites.	Siliceous crystalline rocks.	All other minerals.[1]
Number of mines or quarries	178	83	39	13	16	10	5	12
Number of operators	170	83	36	13	15	6	5	12
Salaried officials, clerks, etc.:								
Number	413	261	67	51	7	6	.....	21
Salaries	$587,005	$391,317	$80,065	$71,155	$2,295	$6,720	.....	$35,453
Wage-earners:								
Average number	5,712	3,349	1,576	487	103	65	1	131
Wages	$5,089,122	$3,176,599	$1,254,090	$439,612	$77,296	$50,225	$330	$90,970
Contract work	$37,054	$28,493	$340	.....	$250	$500	.....	$7,471
Miscellaneous expenses	$761,557	$570,250	$94,123	$71,448	$4,457	$4,460	$63	$16,756
Cost of supplies and materials	$1,835,658	$1,312,176	$196,114	$166,226	$75,046	$5,070	$130	$80,896
Value of product	$12,378,350	$8,500,904	$1,797,454	$1,459,192	$186,663	$105,011	$1,479	$327,647

[1] Includes operators as follows: Asphaltum and bituminous rock, 2; cement, 1; clay, 1; gypsum, 1; iron ore, 4; marble, 2; and sulphur and pyrite, 1.

The mineral resources of Utah constitute one of its principal sources of wealth. The state ranked third in 1902 among the states and territories in the value of gold and silver production and fourteenth in the value of all minerals.

The development of the mineral resources of the state has been slow, principally because of the lack of transportation facilities and to the fact that some of the greatest ore bodies are in almost inaccessible regions. However, the activity in developing properties within the past few years has begun to attract capital, and when the immense bodies of coal, iron, copper, and other ores that the state is known to contain are properly worked, Utah will rank among the foremost mineral producing states of the Union.

Gold and silver mining has been developed to a greater extent than any other branch of the mining industry, and the product of this class of mines in 1902 amounted to $8,500,904, or 68.7 per cent of the entire production from the mines and quarries of the state. The other minerals in the order of their importance are: Coal, bituminous; copper ore; limestones and dolomites; sandstones and quartzites; cement, asphaltum, and bituminous rock; sulphur and pyrite; gypsum; iron ore; marble; siliceous crystalline rocks; and clay.

Natural gas has been produced in Utah, but the wells which were located near Salt Lake City became choked by the decomposition of the slate forming their walls, and the industry in the state has practically been abandoned.[1]

The list of minerals found in Utah but not worked commercially is a long one, including slate, antimony, cinnabar, mineral wax, alabaster, alum, natural gas, precious stones, tripoli and pumice, saltpeter, borax, and many others. In Millard county is found the only known deposit of lump pumice stone in the United States.[2]

Among the gems to be found are some of the most beautiful and brilliant crystals of the North American topaz. These are found in considerable quantities on Thomas mountain, Deseret, an isolated and arid elevation about 6 miles long in Millard county. These crystals are larger than those from California; are always white, and evidently have been decolorized by heat or exposure to sunlight. They are equally as brilliant as those from San Luis Potosi, Mexico, which they closely resemble.[3]

Besides the work done at the productive mines and quarries in 1902, development work was done on 273 mining properties, 266 of which were gold and silver, the others being distributed among the industries of iron and manganese ores, marble, and petroleum. The operators of these properties employed 214 salaried officials, clerks, etc., to whom they paid $162,744 in salaries. They also gave employment to 966 wage-earners, and paid them $920,624 in wages. The work done by contract cost $162,745; the miscellaneous expenses amounted to $133,551, and the cost of supplies and materials was $468,505.

[1] United States Geological Survey, "Mineral Resources of the United States," 1902, page 653.

[2] United States Geological Survey, "Mineral Resources of the United States," 1900, page 196.

[3] Ibid., 1892, page 764.

The relative importance of manufacturing industries closely allied to or based on the mining industry, using as their raw material the product of the mines and quarries, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$21,156,183
Based upon products of mines or quarries:		
Clay, glass, and stone products	$499,372	
Iron and steel and their products	244,542	
Metals and metal products, other than iron and steel	7,595,594	
Miscellaneous industries	783,720	
		9,123,228
All other		12,032,955

As may be seen from the foregoing table, the value of the products of the manufacturing industries of the state based primarily upon minerals mined and quarried was $9,123,228, or 43.1 per cent of all the manufactures in the state. The value of the output of the productive mines and quarries of the state in 1902 was $12,378,350, or 36.9 per cent of the combined value of product of manufactures in 1900 and mines and quarries in 1902.

In 1902 the operators of the productive mines and quarries of Utah gave employment to 5,712 wage-earners and paid $5,089,122 in wages, and in 1900 the manufactures of the state gave employment to 6,615 wage-earners and paid $3,388,370 in wages. The total average number of wage-earners employed in mining and manufactures was 12,327, and $8,477,492 was paid in wages. Mining, therefore, employed 46.3 per cent of the wage-earners and paid 60 per cent of the wages, while manufactures contributed 53.7 per cent of the wage-earners and paid 40 per cent of the wages.

Table 3, compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals of the state, with the exception of copper ore, values for which can not be obtained, from 1890 to 1902.

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Gold and silver.[1]	Coal, bituminous.	Limestones and dolomites.	Sandstones and quartzites.
1890	$11,023,434	$552,390	$27,568	$48,306
1891	11,963,131	666,045	(2)	36,000
1892	11,638,179	562,625	8,000	40,000

[1] Estimates by the Director of the Mint; value of the refined product; silver at coining value. The values in Table 1 are values at the mine.
[2] Not reported separately.
[3] Silver at commercial value.
[4] Census figures, except for gold and silver.

Gold and silver.—Ores of the precious metals were known to exist in Utah in the early days, but mining of most descriptions, and especially of gold and silver, was not encouraged, and it was not until 1862 that any systematic prospecting was done.[1] In that year General Connor, with the Third California Infantry, arrived and established Fort Douglas, near Salt Lake City. Many of the members of his command, who were old California prospectors, were sent out to prospect the territory, and they located mines at Stockton, Bingham Canyon, in Little Cottonwood canyon, and many other localities. Capital was obtained and attempts were made to smelt the lead-silver ore near Stockton about 1866–67, but the conditions were unfavorable, and the net result was a failure at that time. No further general activity in mining the precious metals was reported until about 1870.[2]

Ores of good quality have been found in almost every part of the state, even in the isolated mountains rising out of the desert in western Utah; but any considerable development of mining in that region must await additional facilities, especially those of transportation. From 1870 until 1886 the state's production of these metals was 135,135 fine ounces of gold and 59,065,016 fine ounces of silver.[3]

The following table, compiled from the reports of the Director of the Mint, shows separate values for the annual production of gold and silver from 1890 to 1902:

TABLE 4.—*Value of annual production of gold and silver: 1890 to 1902.*

[Reports of the Director of the Mint.]

YEAR.	Gold.	Silver.[1]	YEAR.	Gold.	Silver.[1]
1890	$680,000	$10,343,434	1897	$1,726,100	$8,100,978
1891	650,000	11,313,131	1898	2,285,400	8,385,810
1892	660,175	10,978,004	1899	3,450,800	9,171,135
1893	853,610	9,304,307	1900	3,972,200	[2]5,745,912
1894	1,128,062	8,448,235	1901	3,690,200	[2]6,456,480
1895	1,373,000	9,655,720	1902	3,594,500	[2]5,740,801
1896	1,899,900	11,413,463			

[1] Coining value. [2] Commercial value.

The production of gold and silver in 1902, while a decrease of $811,379 from that of 1901, was 7.8 per cent of $109,415,000, estimated by the Director of the Mint as the value of the output for the United States in 1902, including silver at its commercial value.

Coal.—The first discovery of coal in Utah was made in 1851 at Coal creek, near Cedar city.[4] Mining was carried on at Wales, Sanpete county, as early as 1855, but only to a limited extent, and no general mining of coal was done until about 1876. There was but a limited development of the industry until 1888 and 1889.

[1] Bancroft's History of Utah, page 740.
[2] Transactions of the American Institute of Mining Engineers, Vol. XVI, page 3.
[3] A Treatise on Ore Deposits, by J. A. Phillips and Henry Louis, page 760.
[4] Harper's Encyclopedia of United States History, Vol. 9, page 535.

It is estimated that over 2,000 square miles of the state's area are underlaid by workable coal, and the outcroppings for hundreds of miles in the central and southern parts are evidences of the great bodies of fuel under the surface, which, with future development, may make Utah one of the greatest coal producing states in the Rocky mountain field.[1]

The industry has made its greatest development within the past five years, the product for 1902 amounting to more than three times the product for 1897. The yearly production since 1889 has shown a steady increase, excepting in 1892 and 1896. Despite the prevailing tendency toward higher prices throughout the coal producing states in 1902, the average price per ton in Utah was only $1.14, as compared with $1.26 in 1901.[2]

The production for 1902 exceeded that of 1901 by 251,907 tons, or 19 per cent, and shows an increase in value of $131,372, or 7.8 per cent. The 39 coal mines reporting in 1902 had a combined output of 1,574,521 short tons, valued at $1,797,454, which places Utah nineteenth and twentieth, respectively, for quantity and value, in the rank of coal producing states. As in 1901, the greater part of the state's production, amounting to over 95 per cent, came from Carbon county.

Table 5, compiled from the reports of the United States Geological Survey, shows the annual production of coal in Utah, from 1876 to 1902.

TABLE 5.—*Annual production of coal, bituminous: 1876 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.
1876	50,400	1890	318,159
1877	50,400	1891	371,045
1878	67,200	1892	361,013
1879	225,000	1893	413,205
1880	225,000	1894	431,550
1881	225,000	1895	471,856
1882	250,000	1896	418,627
1883	250,000	1897	521,560

1885	213,120	1899	786,049
1886	200,000	1900	1,147,027
1887	180,021	1901	1,322,614
1888	258,961	1902	1,574,521
1889	236,651		

Copper ore.—Copper has long been produced from the Utah mines, but until quite recently the metal has been obtained only as a by-product from the smelting of gold and silver ores. Since the development of the mines of the West mountain district, Salt Lake county, the copper output has increased rapidly. The principal producers are in Salt Lake, Beaver, Tooele, Juab, Summit, and Piute counties. Some of the mines in Beaver county are among the most promising to be found anywhere at a similar stage of development.[3]

Utah is fast coming to the front as one of the important copper producing states, and the fact that the output of 23,939,901 pounds of copper, valued at $1,459,192, produced in 1902, is more than six times the production of 1898, shows what extensive development this industry is receiving.

The following table, compiled from reports of the United States Geological Survey, shows the annual production of smelted copper in Utah, from 1883 to 1902:

TABLE 6.—*Annual production of smelted copper: 1883 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Pounds.	YEAR.	Pounds.
1883	341,885	1893	1,135,330
1884	265,526	1894	1,147,570
1885	126,199	1895	2,184,708
1886	500,000	1896	3,502,012
1887	2,500,000	1897	3,919,010
1888	2,131,047	1898	3,750,000
1889	65,467	1899	9,584,746
1890	1,006,636	1900	18,354,726
1891	1,562,098	1901	20,116,979
1892	2,209,428	1902	23,939,901

Limestones and dolomites.—The value of the limestone production of the state for 1902 was $186,663, or more than double that of 1901, and over twenty times that of 1897. The limestone was used principally for burning into lime and as a fluxing material. The following counties, arranged according to the value of their production, contributed to the state's output: Salt Lake, Utah, Weber, Sanpete, Tooele, Summit, and San Juan.

Sandstones and quartzites.—Apparently inexhaustible supplies of Triassic sandstone of various shades of red and pink occur at Red Butte near Salt Lake City, and stones from this formation have been used to some extent in Salt Lake City.[4]

The value of the sandstone quarried in the state in 1902 was $105,011, or nearly three times that for 1901 and over thirteen times that for 1897. In 1902 the following counties contributed to the state's output of sandstone: Summit, Utah, Salt Lake, and Iron.

Siliceous crystalline rocks.—In Little Cottonwood canyon, not far from Salt Lake City, occurs a coarse, light gray granite in seemingly inexhaustible quantities. The stone is apparently of excellent quality and was used in the construction of the Mormon temple.[5] The value of the output of the 5 quarries productive in 1902 was $1,479, a decrease of 73.5 per cent from that for 1901. The value of the granite quarried for monumental work was $984. Beaver, Salt Lake, Utah, and Weber counties contributed to the state's output.

All other minerals.—Utah is exceptionally rich in asphaltum deposits. Bituminous limestone occurs in large quantities, but the excessive cost of transportation may prevent it becoming the source of a profitable industry for some time to come. The streets of Salt Lake City, Ogden, and other cities in the state, are paved with asphaltum produced near by, and the demand

[1] United States Geological Survey, "Mineral Resources of the United States," 1888, page 374.
[2] Ibid., 1902, page 431.
[3] The Copper Handbook, by Horace J. Stevens, Vol. III, page 117.
[4] Stones for Building and Decoration, by George P. Merrill, page 164.
[5] Ibid., page 83.

at present is confined almost wholly to the local trade. Hard varieties of asphaltum such as gilsonite and elaterite occur in several widely separated localities, frequently being associated with ozocerite. The principal localities are at Fort Duchesne in the Uinta reservation and at a place east of this reservation.[1] The gilsonite from the Uinta reservation is an exceptionally pure form of asphaltum. In spite of the fact that it has to be hauled from 70 to 100 miles to the nearest railroad point, its remarkable purity makes it possible to stand the heavy cost of transportation, and a ready market is found for the supply. Most of the output is used in making varnish, but it is also used for various other purposes.[2] No statistics can be shown without disclosing individual operations.

Cement rock of good quality was discovered in 1888 between Ogden and Provo City, and in 1891 the first production of Portland cement from Utah was reported. The plant in operation in 1902 was at Salt Lake City and the stone used came from Parleys canyon, about 10 miles east of the city. The plant had a capacity of 600 barrels per day.[3]

The production of clay in Utah in 1902 was confined to one establishment. The clay mined was used principally for making bricks and tile.

The gypsum deposits of Utah are extensive. The demand in 1902 was for local consumption and only one plant located at Nephi was reported as active.

On the divide between the heads of Big Cottonwood and Snake creeks is a large deposit of marble, which covers many acres and is said to be many hundred feet in thickness. This marble is white in color, and is free from cracks or stains; it can be taken out in blocks as large as it would be possible for the largest machinery to handle.[4] In 1902 but two quarries in the state reported production.

Apparently inexhaustible supplies of iron ore exist in southern Utah, especially in Iron county. Beds of magnetite and hematite that bear evidence of being metamorphosed limonite, occur in limestone of uncertain Silurian age, and associated with eruptive masses, the ore forming great projecting ridges and prominent outcrops, locally called "blow-outs." These deposits occur over an area 15 by 5 miles and are in the southern end of the Wasatch mountains. The samples show rich ores, which at times exceed the Bessemer limit of phosphorus. The importance of these deposits lies in the future. They are the largest in the West, and are interesting in their bearing on the general origin of magnetite.[5] The 4 productive mines produced 16,240 tons of ore in 1902, valued at $27,417. The counties contributing to the output were Millard, Juab, and Utah.

The sulphur beds of Utah extend over a large area and in places are of remarkable purity, but the excessive cost of transportation and the development of the sulphur beds of Louisiana and other points more accessible to the market have, however, tended to curtail the production in Utah. The principal source of the production is Beaver county.

VERMONT.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Vermont for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Marble.	Siliceous crystalline rocks.	Slate.	Limestones and dolomites.	All other minerals.[1]
Number of mines or quarries	192	22	74	76	14	6
Number of operators	160	16	68	58	13	5
Salaried officials, clerks, etc.:						
Number	433	195	128	97	12	1
Salaries	$376,077	$184,877	$104,655	$78,442	$7,953	$150
Wage-earners:						
Average number	5,398	2,074	1,505	1,639	156	24
Wages	$3,114,399	$1,206,208	$958,950	$874,263	$65,083	$9,895
Miscellaneous expenses	$382,734	$226,103	$70,653	$79,700	$5,810	$468
Cost of supplies and materials	$1,076,143	$523,075	$272,888	$162,410	$116,301	$1,469
Value of product	$5,904,705	$2,628,164	$1,570,423	$1,464,918	$225,703	$15,497

[1] Includes operators as follows: Buhrstones and millstones, 1; clay, 2; iron ore, 1; mineral pigments, crude, 1; oilstones, whetstones, and scythestones (1 quarry—operator reported in Arkansas).

The great bulk of the mineral wealth of Vermont lies in its vast rock deposits, comprising marble, granite, limestone, slate, etc. The quarrying of these rocks began more than a hundred years ago, and at an early date some of them, notably marble, granite, and slate, brought the state into national prominence; later, through superiority of quality and especial fitness for certain uses, these products were shipped beyond the limits of the United States and found a market in practically every civilized country of the world.[1]

The range of metalliferous ores in the state is quite limited, and these, excepting copper, have not been found in such quantities as to warrant extensive exploitation.

There are several minerals occurring in the state for which no production in commercial quantities was reported in 1902. Among them is asbestos, which was discovered at numerous places in the state many years ago. It has been during the last few years only, however, that any systematic development of the deposits has been attempted.[2] In 1902 these operations were carried on in the north central part of the state, in the towns of Eden, Lamoille county, and Lowell, Orleans county.[3] The Vermont asbestos is of good quality and exists in great abundance.

Copper ores occur extensively in eastern Vermont, particularly in Orange county, and considerable quantities have been extracted in the past. In this region there were four mines, one of which was worked long before the development of the Lake Superior mines, and reached a depth of over 1,500 feet.[4] The present owners have expended large sums in installing new and modern machinery and methods, and have given evidence of an intention to develop the property on a large scale.[5]

Ilmenite, the most abundant of all the titanium minerals, occurs to some extent in combination with varying quantities of ferric oxide. Rutile, one of the allied minerals, also occurs in the state.[6]

Mica, while of quite general occurrence throughout the state in the form of small flakes, has been found in deposits of commercial importance in only one locality. This bed is at Sherburne.

Talc and soapstone have been found and mined in Vermont, although there was no production reported for 1902. The known deposits occur in many localities in the state, notably in Grafton,[7] and operations are being resumed at Rochester, Windsor county, on a property which was worked rather extensively during 1865 and 1866.[8]

Gold has been found in small quantities at some places in the state, but its mining has not proved profitable.

The relative importance of manufacturing industries closely allied to or based upon the mining industry, using as their raw material the products of mines and quarries, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$57,623,815
Based upon products of mines or quarries:		
Chemicals and allied products	$407,337	
Clay, glass, and stone products	6,936,749	
Iron and steel and their products	4,939,690	
Metals and metal products, other than iron and steel	410,643	
Miscellaneous industries	1,319,382	
		14,013,801
All other		43,610,014

Table 2 shows that the total value of the state's manufactures in 1900 amounted to $57,623,815, and that of this sum $14,013,801, or 24.3 per cent, was the value of the product of manufacturing establishments using as their raw material the products of mines and quarries. For 1902 the reported value of the output of the mines and quarries of the state was $5,904,705, or 9.3 per cent of the combined value of the state's manufactures in 1900 and mining and quarrying in 1902.

As reported at the census of 1900, the manufactures of the state employed on an average 29,455 wage-earners during the year and paid $12,237,684 in wages. The corresponding figures for mines and quarries in 1902 were 5,398 wage-earners and $3,114,399 paid in wages. Comparing the figures for manufactures and mines and mining, it is seen that manufactures employed 84.5 per cent of the wage-earners and paid 79.7 per cent of the wages, while mines and quarries gave employment to 15.5 per cent of the wage-earners and paid 20.3 per cent of the wages.

The following table, compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals of the state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Marble.	Siliceous crystalline rocks.	Slate.	Limestones and dolomites.
1890	$2,169,560	$581,870	$842,013	$195,066
1891	2,200,000	700,000	955,617	175,000
1892	2,275,000	675,000	1,014,000	200,000
1893	1,621,000	778,459	535,732	151,067
1894	1,500,399	893,956	658,167	408,810
1895	1,321,598	1,007,718	625,331	300,000
1896	1,101,557	895,516	609,596	147,138
1897	2,050,229	1,074,300	695,815	165,657
1898	2,067,938	1,084,218	732,684	174,150
1899	2,241,806	1,212,967	872,673	282,173
1900	2,484,852	1,113,788	917,462	188,100
1901	2,753,583	1,245,828	1,162,191	205,138
1902	2,628,164	1,570,423	1,464,918	225,703

Marble.—Vermont leads all other states in the production of marble. The total value of the output of this stone in the United States in 1902 was $5,044,182, and of this amount Vermont contributed $2,628,164, or 52.1 per cent.

Marble has been quarried in Vermont for more than a century, the earliest authentic record of such work having been made in 1785.[1] In 1902 the state's output of marble came from the quarries in Rutland, Bennington, Franklin, Chittenden, and Grand Isle counties, though the stone is of known occurrence at many other localities in the state.[2] The most famous of Vermont marble beds are those of West Rutland, and the name "Rutland marble" is used to designate either that from these quarries or from Proctor.[3] Important quarries are also located at Dorset and East Dorset, in Bennington county. Much of this stone is of the finest quality and is used for monuments, decorative work, and for statues, as well as for general building purposes.[4]

The color effects of Vermont marble are many and beautiful, ranging from pure white through all shades of blue, and sometimes green, to deep blue-black, often being beautifully mottled and veined. The dark varieties, as a rule, are the most durable and valuable, although the white is in the greatest demand for monumental and statuary work. This stone differs from the marble of Italy in being of a dead white color and lacking the luster so characteristic of the Italian product. Marbles of different shades of gray, with sinuous veins, as well as some of red, pink, and chocolate colors, plain and mottled, are also found.[5] Black marble is found at Isle La Motte, in Grand Isle county.

Since the deposits in Vermont are of great thickness, the quarries occasionally reach a considerable depth, or in following the vein the opening is pushed far under a hill and forms a cavern, the walls and roof of which are supported at intervals by enormous piers left for that purpose.

The value of the marble, both rough and dressed, that was used for monumental purposes, amounted to $758,390, or 28.8 per cent of the total, while the value used for building purposes amounted to $433,265, or 16.5 per cent of the total.

Siliceous crystalline rocks.—The occurrence of extensive granite deposits in Vermont has been known since the state was first settled.[6] Notwithstanding this knowledge, the quarrying of granite as an industry of importance has had its growth almost entirely since 1880, although small quantities of the stone were taken out much earlier.[7] Granite has been uncovered in appar-

ently inexhaustible quantities in all parts of the state, though the center of the granite quarrying industry is at Barre and Woodbury, in Washington county. In fact, the former place, now a thriving city, owes practically its whole importance to the quarrying of this stone.[1]

Vermont granites vary in color, from light to dark gray and range in texture from coarse to very fine.[2] The granite of Barre, is of the best quality known, and is used to a very large extent for monuments and fine decorative work, because it takes a fine polish, and stands exposure to weather without apparent injury.[3] The stone occurs in thick strata, and can be taken out in immense blocks which adds greatly to its value as a structural material.[4]

In 1902 Vermont ranked third among the granite producing states with a product valued at $1,570,423, or 26.6 per cent of mineral output of the state, and 8.6 per cent of total value of product of the industry in this country.

The value of the granite, both rough and dressed, that was used for monumental purposes, amounted to $1,209,194, or 77 per cent of the state's production, while the value of that used for all other purposes amounted to $361,229, or 23 per cent.

Slate.—Although slate is found in a majority of the counties of the state, there are three distinct belts traversing the eastern, middle, and western parts of the state. Of these, the western belt, especially that section lying in Rutland county, is by far the most important, and it is here that the well-known quarries at Castleton, Fair Haven, Poultney, Wells, and Pawlet are located.[5]

The first slate quarry in Vermont is said to have been opened in 1805,[6] although the year 1839 is usually considered to be the date of the beginning of the industry in the state. It was, however, not until 1845 that the quarrying of this stone began to assume the proportions of an important branch of the mineral industry of the state.[7]

In Vermont slate is found in many colors, the most common of which are green, purple, black, red, and chocolate, with the variegated or mottled varieties,[7] a single quarry not infrequently producing several different colors of stone. Of the green shades, there are two classes known as "sea green" and "unfading green," both being used extensively for roofing purposes, the unfading green retaining its color permanently, while the sea green, upon exposure to weather, turns to a yellowish brown. The quality of the two is about the same, and where fine artistic effect is not sought the sea-green variety is equally satisfactory.[8]

The quarries are all open pits, ranging in depth to as much as 300 feet. The quarrying of slate is attended by an enormous waste of material, not more than one-sixth of the total quantity of rock removed being available for use, and the dump piles grow with such rapidity and to such size as to become a serious hindrance to the progress of the work.[9]

The state's product of slate in 1902 amounted in value to $1,464,918, or 24.8 per cent of the total value of its output of all minerals. Of this amount, 91.4 per cent was used for roofing purposes. Vermont ranked second among the states in 1902 in the production of slate, and the output was valued at 25.7 per cent of the total yield of the country. It was put to the usual uses, including roofing, school slates, beds for billiard tables, etc. Large quantities of domestic slate are exported and the demand increases steadily.[10]

Limestones and dolomites.—The most important deposits of limestone are found in Washington and Orange counties.[11] The stone has been quarried on the southern end of Isle La Motte for over a century, the quarry being nowhere much below the level of the lake.[12] The stone is thickly bedded, thus permitting the removal of blocks 15 or 16 feet in thickness, and ranges in color from white to dark gray or black. The value of the stone burned for lime formed 97.2 per cent of the total product.

All other minerals.—The only quarry credited to Vermont as having produced buhrstones and millstones in 1902 is in Rutland county.

Clay has been found in Grand Isle county, some of the deposits being 25 feet thick, and in small quantities in various other parts of the state.[13] In 1902 a production was reported by two establishments located in Bennington county.

An iron ore mine located near Brandon, Rutland county, reported a small production for 1902. The ore has also been found at Monkton, Bennington, and other localities, mostly in the southern part of the state.[14] It usually occurs in the form of bog ore and limonite, and was first discovered at Brandon in 1810, soon after which a forge and furnace were erected there. In the same vicinity ocher has been discovered.[15]

In 1902 small amounts of ocher, iron, and metallic substances were extracted in Rutland county and, being ground for paints, were classified as crude mineral pigments. Aside from the small value they added to the total mineral output of Vermont, these serve chiefly to show the diversity of Rutland county's mineral wealth.

There was one quarry in Orleans county from which a production of oilstones, whetstones, and scythestones was reported in 1902.

VIRGINIA.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Virginia for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Iron ore.	Limestones and dolomites.	Sulphur and pyrite.	Cement.	Siliceous crystalline rocks.	Slate.	Manganese ore.	All other minerals.[1]
Number of mines or quarries	192	26	62	37	6	3	17	4	6	31
Number of operators	140	22	25	28	4	3	17	4	6	31
Salaried officials, clerks, etc.:										
Number	700	179	257	63	32	43	21	15	10	80
Salaries	$546,204	$155,930	$174,034	$35,459	$29,970	$44,675	$12,904	$11,490	$4,241	$77,501
Wage-earners:										
Average number	8,993	3,004	2,686	890	655	178	469	247	113	751
Wages	$3,458,450	$1,407,867	$888,958	$290,979	$222,986	$83,423	$190,322	$97,645	$33,903	$242,367
Contract work	$35,964	$27,600	$6,730		$1,134					$500
Miscellaneous expenses	$603,290	$315,384	$120,563	$24,898	$23,285	$31,487	$12,466	$24,366	$600	$50,241
Cost of supplies and materials	$928,387	$215,458	$201,426	$126,956	$137,491	$91,100	$22,290	$20,964	$8,691	$104,011
Value of product	$6,607,807	$2,543,595	$1,652,799	$535,113	$501,642	$327,659	$282,046	$160,951	$29,444	$574,558

[1] Includes operators as follows: Asbestos, 1; barytes, 3 (4 mines); buhrstones and millstones, 3; copper ore, 1; flint, 1; gold and silver, 5; gypsum, 2; infusorial earth, tripoli, and pumice, 2; lead and zinc ore (2 mines—operator reported under iron ore); marl, 1; mica, 2; mineral pigments, crude, 2; precious stones, 3 (no mines); rutile, 1; sandstones and quartzites, 2; talc and soapstone, 2.

The range of mineral industry in Virginia in 1902 was wide and varied, comprising within its scope the production on a commercial scale of twenty-four different minerals. First among these in point of value was the production of bituminous coal, obtained in the main from the vast deposits of high-grade steam and coking coal in the southwestern part of the state. It is this region that furnishes the celebrated Pocahontas coal. Iron ore, which was extensively produced in 1902, occurs among the mountains in deposits of remarkable richness, the beds of ore being from 20 to 100 feet in thickness and many miles long. For 300 miles the western foothills of the Blue Ridge are lined with brown hematite ore and solid masses of it appear along the Alleghenies.[1] The yield of brown hematite from this region comprises an important percentage of the total output of this variety in the country, and also constitutes the bulk of iron ore production in the state.

The industry of manganese ore mining had its beginning in Virginia, and more than one-half of the total output of this mineral in the United States has been contributed by the mines of this state, during the third of a century of manganese ore exploitation in the country.

The lead and zinc deposits of Wythe county have been worked for more than a hundred and twenty-five years, and furnished lead to both the Continental and Confederate Armies.[2]

The great gold belt, 200 miles in length, which stretches from the Potomac to the Dan, has furnished more than $2,000,000 worth of gold to the Mint.[1]

The copper deposits of the state are extensive, especially in southwestern Virginia,[3] and the noted deposits of Louisa county have long been the seat of an important industry.[1]

The sandstones of the Blue Ridge, the limestones and slates of the valleys, and the granites which are widely distributed afford an abundant supply of building materials, and their exploitation constitutes an important industry in the state.[4]

From the fertilizing marls and greensands of Tidewater westward to the vast coal and metalliferous deposits near the Kentucky and West Virginia lines is spread a great variety of mineral wealth, which affords such basis as to make the mining industry an important factor in the industrial activity of the state.

The following is a list of minerals of known occurrence in Virginia which were not produced commercially in 1902: Allanite, alum, arsenic, bismuth, carbonite, feldspar, fire clay, kaolin, marble, plumbago, quartz, serpentine, and tin.

Work of a developing character, where no production was realized from the mining properties, was reported by 5 operators, and was confined during 1902 to gold and silver and manganese ore. These operators

[1] King's Handbook of the United States, page 858.
[2] Transactions of the American Institute of Mining Engineers, Vol. V, page 85.
[3] Transactions of the American Institute of Mining Engineers, Vol. V, page 81 ff.
[4] The New International Encyclopedia, Vol. XVII, page 374.

paid $4,535 to 8 salaried officials, clerks, etc., during 1902, and gave employment to an average number of 51 wage-earners who received $17,964 in wages. Contract work amounted to $158, miscellaneous expenses to $9,752, and the cost of supplies and materials to $26,305.

The relative importance of manufacturing industries closely allied to or based upon the mining industry, using as their raw material the products of mines and quarries, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$132,172,910
Based upon products of mines or quarries:		
Chemicals and allied products	$4,483,348	
Clay, glass, and stone products	2,121,495	
Iron and steel and their products	13,549,769	
Metals and metal products, other than iron and steel	1,698,151	
Miscellaneous industries	5,419,838	
		27,272,601
All other		104,900,309

The total value of the products of the manufacturing industries based upon mining was $27,272,601, or 20.6 per cent of the total value of the product of all manufacturing industries in the state in 1900. During the same year there were employed in all branches of manufacture in the state 72,702 wage-earners, who were paid $22,445,720 in wages. In 1902 there were employed in the mines and quarries of the state 8,993 wage-earners, who received $3,458,450 in wages. Comparing the figures for these two branches of industry, it will be seen that 89 per cent of the wage-earners, receiving 86.6 per cent of the wages, were employed in manufacturing, while 11 per cent of the wage-earners, receiving 13.4 per cent of the wages, were employed in mining.

The following table, compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals of the state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Iron ore.	Limestones and dolomites.	Cement.	Siliceous crystalline rocks.	Slate.	Manganese ore.

Coal.—The mining of coal in Virginia, and in the United States, began in 1775, near Richmond; its occurrence in this locality, however, had been noted some five years earlier.[1] From the beginning of the industry of coal mining until 1789 the entire output went to supply the local demand. During 1789 the product of the mines began to find a wider market in the northern cities, and for many years the bituminous coal deposits of the Richmond basin were the only source from which this mineral could be procured and shipped coastwise.[2] The product sent out in this way to other cities had grown in 1822 to 48,000 tons and in 1833 to 143,000 tons.[2] About this time the discovery and development of other coal areas carrying deposits of superior quality and more economical of exploitation caused a rapid decline in the output of this region. By the middle of the century the production of coal in this field had practically ceased. For more than a quarter of a century the output of coal in the state was insignificant, but the building of the Norfolk and Western Railway, in 1883, was followed by the development of the great coal deposits of southwestern Virginia, notably the Pocahontas region, and the state soon came again into prominence as a coal producer. In 1880 the total coal production of the state was only 112,000 short tons, but in 1889, or seven years after operations in the new fields were under way, the output had increased to 865,786 short tons, and in 1902 had reached a total of 3,182,993 short tons.

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of coal in the state from 1822 to 1902:

TABLE 4.—*Annual production of coal, bituminous: 1822 to 1902.*

The coal deposits of the state occur in two distinct areas. The first of these, that in which the industry

[1] United States Geological Survey, Twenty-second Annual Report, Part III, page 38.
[2] Statistics of Coal, by R. C. Taylor, page 21.

of coal mining in the country had its inception, comprises the counties of Henrico, Chesterfield, and Goochland, and parts of Powhatan and Amelia; the second, and by far the more important field of the state, is a part of the great Appalachian region and lies in the southwestern part of the state.[1] Perhaps the most remarkable and valuable occurrence of bituminous coal to be found in the United States in association with vast deposits of metalliferous ores is that forming the southeastern portion of the Kanawha basin and comprising Tazewell, Russell, Scott, Buchanan, Wise, and Lee counties.[2]

Iron ore.—Probably the first iron ore mining in the New World occurred in Virginia, for on April 10, 1608, a ship belonging to the Virginia Company of London sailed from Jamestown loaded with iron ore and other commodities, reaching England on May 20. The record of this first exploitation of American ore by Europeans states that this ore was smelted and 17 tons of metal were sold at £4 per ton.[3]

For several years following numerous attempts were made by the Virginia Company to establish the industry of iron manufacture in the vicinity of Falling creek. Under the direction of John Berkley, who was sent out by the company in 1621, the construction of several plants for the reduction of the ore was begun. However, just when these works were nearing completion and the prospects for a rapid development of the industry were bright, the colony was massacred by the Indians, on March 22, 1622. There is no record of further efforts to manufacture iron in the colony for many years. In 1687 and again in 1696 Col. William Byrd set on foot a plan to rebuild these works, but the project never materialized.[4]

In the eighteenth century, however, the colony became very prominent in the manufacture of iron and fulfilled in an eminent degree, though at a much later day, the expectations which had been entertained of its iron producing capabilities by the enterprising but unfortunate Virginia Company of London.[4]

To Col. Alexander Spotswood, who was governor of the colony from 1710 to 1723, has been accredited the honor of establishing the iron industry of the state on a firm and permanent basis. During this period a colony of German Protestants settled at the head of the Rappahannock river, with the hope of locating mines. It is probable that the first furnace in the state was owned by Governor Spotswood and was built and operated in 1715 or 1716 by these German miners, who were in his employ.[5]

The industry of iron making, the growth of which was stimulated by encouragement from the colonial government, spread rapidly into other localities and at the beginning of the Revolution was an important factor in the industrial development of the colony.[6]

In common with other industries, iron making took a fresh start subsequent to the War of the Revolution and for many years no state in the Union gave closer attention to domestic manufactures than Virginia. As the result of various causes, however, the iron industry in Virginia declined rapidly toward the middle of the nineteenth century and by 1856 many of the furnaces and forges had been abandoned.[6]

A new era of activity in iron working in Virginia opened, however, with the discovery of vast deposits of high-grade ore in the southwestern part of the state. This was followed by extension of railroads into the region and the exploitation of the celebrated coal deposits of the Pocahontas Flat Top district, and has resulted in a reawakening in the industry that has again brought the state into prominence as an iron producer.[7]

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of iron ore in the state from 1890 to 1902:

TABLE 5.—*Annual production of iron ore: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

[1] Includes production from West Virginia.

Limestones and dolomites.—The predominating rocks of the region west of the Blue Ridge are the limestones. This region has long been famous for the occurrence of natural curiosities in the limestone formations, such as Weyers cave, in Augusta county, the caves of Luray, in Page county, and the Natural Bridge, the arched remnant of a cave, in Rockbridge county.[8]

The limestones have been quarried extensively at numerous places, but have been used to only a very limited extent for building purposes, the bulk of the output being utilized for making lime and as a flux in the reduction of ores.

Sulphur and pyrite.—The extensive pyrite deposits of the state, and especially those of Louisa county, where practically inexhaustible quantities occur, have long been exploited. The bulk of the product of these mines has gone into the manufacture of sulphuric acid, the demand for which commodity has increased materially during the last decade, as a result of its extended use in the manufacture of paper from wood pulp and in the manu-

facture of superphosphates from phosphate rock, in which latter process a chemically pure sulphuric acid is not essential and that made from pyrite serves the purpose equally as well as that made from sulphur.[1]

In the production of pyrite, the importance of which is rapidly increasing, Virginia took first rank in 1902, with an output valued at $501,642, or 64.7 per cent of the total yield of this mineral in the United States.

Cement.—The industry of the manufacture of cement from natural rock in Virginia dates from 1835 and had its beginning in Rockbridge county. The quality of this first product was excellent. Works were established at Balcony Falls in 1848; subsequently this plant was destroyed by flood and later was rebuilt on a more extended scale at Locker, a short distance away, where it is at present in operation and enjoys the distinction of being the oldest active cement plant in the state. Another large and important cement plant is located near Staunton, at Craigsville. It was built in 1900, and in 1902 contributed an important percentage of high-grade cement to the total output of this mineral in the state.[2]

Table 6, compiled from the reports of the United States Geological Survey, shows the annual production of cement from 1890 to 1902.

TABLE 6.—*Annual production of cement: 1890 to 1902.*

[1] Includes production from West Virginia.
[2] Included in the production of Ohio.

Siliceous crystalline rocks.—The production of building stone has long been an important industry in the state, and the output of the Virginia granite quarries has been used in many notable structures. Among these is the State, War, and Navy Department building at Washington.[3]

The siliceous crystalline rocks of the state are confined in the main to a belt or zone running from Alexandria county through Fairfax, Fauquier, Spottsylvania, Henrico, Goochland, Chesterfield, Dinwiddie, and Greenesville counties, into North Carolina. While a wide area of occurrence is comprised within this belt, the outcrops of quarriable granite are confined to a very limited part of this region, the principal points being in Chesterfield and Dinwiddie counties, on the James river, and in the immediate vicinity of Richmond.

The product of the quarries in the vicinity of Richmond and of those in Chesterfield county is a massive gray granite, well adapted for general building purposes, paving stone, and monumental work. This granite has found a market in practically all the states and cities south of New England and as far west as Nebraska.[3]

Slate.—The occurrences of slate in deposits of commercial importance are distributed over a considerable area in Virginia and have been exploited in numerous places. The principal producing district in 1902, and that within which the industry of slate quarrying in the state most probably had its origin, was in Buckingham county.[4] Smaller products were also reported from Amherst and Albemarle counties. Abundant deposits of this mineral have been found and developed to a limited extent in the Great Valley and Appalachian districts.[5]

Manganese ore.—The beginning of manganese ore mining in Virginia, and perhaps in the United States, occurred in 1857 in the Shenandoah valley, about 100 tons being taken out during that year. In 1868 and 1869 about 5,000 tons of manganese ore were taken out near Warminster, and this marks the beginning of systematic manganese ore mining in the state.[6]

For many years the states of Virginia and Georgia have contributed the bulk of the output of this valuable mineral in the United States, nearly all the yield being exported to England. The period of greatest activity in manganese mining in the state was that beginning in 1885 and closing with 1891, during which years the average annual production was about 15,000 tons, the maximum output occurring in 1886, when the total was 20,567 long tons. There has been a marked decline in the state's production in recent years.

Table 7, compiled from reports of the United States Geological Survey, shows the annual production of manganese ore in the state from 1880 to 1902, inclusive, during which period the state contributed more than 55 per cent of the total output of this mineral in the country.

TABLE 7.—*Annual production of manganese ore: 1880 to 1902.*

The known occurrences of manganese ore in the state are widely distributed, being practically coextensive with its area. Beginning with the pocket occurrences in the eastern part or Tidewater district, manganese ore has been found and mined in the Midland, Piedmont, Blue Ridge, Valley, Appalachia, and trans-Appalachia divisions westward to the West Virginia line. The great bulk of the state's output, however, has come from the Valley region.[1]

All other minerals.—Asbestos, which occurs in numerous places in western and southwestern Virginia,[2] was mined to a limited extent during the year. Barytes of good quality and in large quantities occurs at many points in the southern and southwestern parts of the state, notably in Campbell county in the vicinity of Lynchburg,[3] and its mining has for many years been of relative importance. The output of this mineral in Virginia in 1902 comprised more than one-fifth of the total production in the country.

Buhrstones and millstones were obtained from granitic rocks at several places in the state, the production for 1902 constituting nearly 20 per cent of the total value of production of the United States.

Copper ores occur extensively in southwestern Virginia and in some other sections of the state, especially in Louisa county near Talersville.[4] Copper was produced on a commercial scale in 1902 at only one mine.

Virginia became a producer of flint in 1902, though the output was small and was confined to one mine.

Gold and silver in a limited way has been a mineral product of the state for more than a century and a quarter. The first recorded discovery of gold in the state was that noted in the papers of Thomas Jefferson. About 4 miles below the falls on the Rappahannock river there was found a lump of ore weighing 4 pounds; this yielded, when treated, 17 pennyweights of gold.[5] Gold is of wide occurrence in the state, and extensive mining operations have been prosecuted at different times over a wide area. The principal deposits occur within the Virginia gold belt, which extends from the Potomac river to Halifax county, a distance of about 200 miles, with a width varying from 15 to 25 miles.[6]

Gypsum, the producing localities of which are the Holston river fields around Saltville, was mined in 1902 to a limited extent at two points, though in former years large quantities of this mineral were taken out.[7]

An extensive bed of infusorial earth is traceable from the Patuxent river in Maryland to the Meherrin in Virginia. Exposed patches occur at Richmond and other points.[8] The output in 1902 was limited to the production of two concerns.

A small quantity of lead ore was produced in 1902 at two mines, the work being carried on in connection with the mining of iron ore. Extensive deposits of lead ore occur in southwestern Virginia, and lead mining was begun in this region more than a century ago.[9]

The marls which occur in the eastern part of the state were mined to a limited extent during the year, one establishment reporting production. Virginia and New Jersey mined the entire production of marl in the United States in 1902.

Mica occurs in numerous places, notably in Hanover, Goochland, Bedford, Henry, and Amelia counties.[6] The production in 1902 was from two mines.

Mineral paints were produced to a limited extent during the year in Bedford and Page counties.

While no mining operations were prosecuted for precious stones, specimens of value were picked up in a number of places.

Deposits of rutile occur on both sides of the Tye river near Roseland post office, in Nelson county, and the production of this mineral during the year was confined to the output of one company operating in this vicinity.

Sandstones and quartzites were quarried during the year on a commercial scale at two points. The occurrence of these rocks in the state is extensive.[9]

Numerous occurrences of soapstone have been noted in the state, notably in the southern and southwestern parts. In Campbell county there is a continuous belt traceable for miles.[10] The product of the state in 1902 was reported from two mines.

WASHINGTON.

Table 1 is a summary of the statistics for the productive mines and quarries of the state of Washington for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Gold and silver.	Limestones and dolomites.	Siliceous crystalline rocks.	Marble.	Sandstones and quartzites.	All other minerals.[1]
Number of mines or quarries	90	27	31	12	9	5	3	3
Number of operators	84	22	31	12	8	5	3	3
Salaried officials, clerks, etc.:								
Number	258	160	34	22	20	12	4	6
Salaries	$328,289	$221,915	$36,065	$35,701	$11,948	$10,400	$4,100	$8,160
Wage-earners:								
Average number	4,567	3,931	229	147	137	63	32	28
Wages	$3,735,484	$3,220,263	$232,058	$87,850	$95,949	$46,099	$23,237	$30,028
Contract work	$29,600	$200	$29,400					
Miscellaneous expenses	$225,161	$180,213	$23,651	$8,498	$2,644	$9,350	$350	$455
Cost of supplies and materials	$615,807	$473,254	$55,668	$28,425	$21,264	$22,349	$4,315	$10,532
Value of product	$5,393,659	$4,572,295	$338,351	$213,814	$147,273	$61,176	$30,725	$30,025

[1] Includes operators as follows: Clay, 1; copper ore, 1; molybdenum, 1.

The large, mountainous area abounds in rich deposits of useful and precious minerals awaiting only the further progress of development operations and improved transportation facilities to become valuable workings. The coal fields have thus far received the greatest attention, the product of coal mines in 1902 amounting to 84.7 per cent of the total mineral production in the state.

There was no production, on a commercial scale, of iron ores in 1902, although deposits of considerable extent are known to occur in the state. The iron ores found in Washington are magnetites, hematites, limonites, and mixtures of hematite and magnetite, and the localities of principal occurrence are in Skagit, King, Kittitas, Stevens, and Mason counties, while bog ore is found in Whatcom, Clallam, Spokane, Whitman, Thurston, and Jefferson counties.[1] Galena is about the only lead ore found in the state and it occurs chiefly in association with other sulphides, as does also zinc, which is found in small quantities in the form of sphalerite or zinc-blende.[2]

The occurrence of platinum has been reported, but the deposits have not been sufficiently rich to place the extraction of this metal on a paying basis. Nickel ore is said to exist in Ferry county, and deposits of tungsten are found in some parts of the state, but no mines have been developed. Petroleum is obtainable in many of the coal regions, but has not been produced in commercial quantities.

[1] Washington Geological Survey, Vol. I, pages 224 to 227.
[2] Ibid., pages 40 and 41.

One hundred and fifty-one operators in the state of Washington reported a total expenditure of $1,022,397 for development without production during 1902. This amount includes salaries and wages, miscellaneous expenses, cost of supplies and materials, and contract work, and represents an outlay greater than one-fifth of the total expenditures reported by the 90 producing mines and quarries in the state. Of the 151 mines reporting development work, 143 were gold and silver mines with expenses amounting to $989,812, or 96.8 per cent of the total disbursements for this purpose.

Mineral products form a basis for manufacturing industries to a large extent, being used as raw or partially manufactured material. The following table shows the extent to which the manufacture or remanufacture of mine and quarry products into manufactured products prevails in the state of Washington:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$86,795,051
Based upon products of mines or quarries:		
Chemicals and allied products	$69,500	
Clay, glass, and stone products	1,056,545	
Iron and steel and their products	2,592,946	
Metals and metal products, other than iron and steel	4,867,672	
Miscellaneous industries	5,562,302	
		14,148,965
All other		72,646,086

As shown by the above table the products of those manufactures bearing intimate relation to mining or quarrying represent 16.3 per cent, or almost one-sixth of the total value of the products of all manufacturing industries in the state.

The total mine and quarry production during 1902 was valued at $5,393,659, or 5.8 per cent of the combined products of manufactures in 1900 and mines and quarries in 1902.

During 1900 there were employed in all branches of manufactures in the state 33,806 wage-earners who were paid $19,106,873 in wages. In 1902 there were employed in the mines and quarries of the state 4,567 wage-earners who received $3,735,484 in wages. Comparing the figures for these two branches of industry, it is seen that 88.1 per cent of the wage-earners, receiving 83.6 per cent of the wages, were employed in manufacturing establishments, while 11.9 per cent of the wage-earners, receiving 16.4 per cent of the wages, were employed in the mines and quarries of the state.

The following table, compiled from reports of the United States Geological Survey, shows the value of the annual production of the principal minerals from 1890 to 1902:

TABLE 3.—VALUE OF ANNUAL PRODUCTION OF PRINCIPAL MINERALS: 1890 TO 1902.

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Silver.[1]	Gold.[1]	Limestones and dolomites.	Siliceous crystalline rocks.	Marble.	Sandstones and quartzites.
1890	$3,426,590	$90,505	$204,000	$231,287	(2)	(3)	$75,936
1891	2,437,270	213,334	335,000	25,000	(2)	(3)	75,000
1892	2,763,547	214,238	373,561	100,000	(2)	(3)	75,000
1893	2,920,876	197,430	222,100	139,862	(2)	(3)	15,000
1894	2,578,441	12,520	232,761	59,148	(2)	(3)	6,611
1895	2,577,958	158,640	351,000	75,910	(2)	(3)	14,777
1896	2,396,078	355,426	405,700	83,742	(2)	(3)	11,090
1897	2,777,687	138,214	419,900	126,877	$5,800	(3)	16,187
1898	3,352,798	328,921	766,200	140,239	9,700	$3,600	15,575
1899	3,603,989	330,990	685,400	139,339	42,766	4,837	58,395
1900	4,700,068	[4]139,190	718,200	249,163	48,900	11,836	68,133
1901	4,271,076	[4]206,640	580,500	234,587	43,808	22,816	89,174
1902	4,572,295	[4]328,070	272,200	213,814	147,273	61,176	30,725

[1] Estimates of the Director of the Mint, the values being for the refined product; silver at coining value. The values in Table 1 are the values at the mine.
[2] Not reported separately.
[3] Not reported.
[4] Commercial value.

There has been a noticeable growth in the mining industry during the last decade. With the construction of railways into mining and quarrying districts, more extensive development of the mineral resources of the state should speedily follow. Metalliferous deposits occur in many parts of the state,[1] the sulphide ores appearing in greatest abundance. Arsenides and antimonites are also found, but oxides and carbonates are somewhat less plentiful. The value of the nonmetallic mineral product during 1902 greatly exceeded that of the metallic, because of the extensive operations in coal mining and stone quarrying.

Coal, bituminous.—The first discovery of coal[2] was in the Cowlitz valley during 1848, but the quality was inferior. The occurrence of coal on the Stilaguamish river[3] was known as early as 1851, and deposits near Bellingham bay were discovered in 1852. In the following year the Sehome coal deposit, and that on the Black river not far from Seattle, were opened. In 1863 coal was discovered at Gilman and also near Lake Washington, and at a later date the Green river and other coal fields were found.

The character of the coal produced is chiefly lignite, although it often ranges to a bituminous or a semi-bituminous variety. Washington is the only one of the Pacific states in which coal of a coking quality has been mined, all the coal produced thus far in California and Oregon having been lignite.

The principal coal fields of the state are located in Kittitas, King, Pierce, Skagit, Whatcom, and Lewis counties in the order named, and important outcroppings have been noted in Lincoln, Spokane, Thurston, and other counties. The production increased phenomenally from 145,015 short tons, valued at $389,046, in 1880, to 1,263,689 short tons, with a value of $3,426,590, in 1890, an increase of 771.4 per cent in the quantity and 780.8 per cent in value. During the period of twelve years from 1890 to 1902 the increase in quantity was 112.2 per cent, and in value 33.4 per cent.

In 1902 the state ranked fifteenth in the United States in coal production, the total value of the product reported in that year being over $4,500,000. Table 4, compiled from reports of the United States Geological Survey, shows the annual production of coal from 1870 to 1902.

TABLE 4.—*Annual production of coal, bituminous: 1870 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Short tons.	YEAR.	Short tons.	YEAR.	Short tons.

[1] Washington Geological Survey, page 39.
[2] History of the Pacific States, by Hubert H. Bancroft, Vol. XXVI, page 340.
[3] Washington Geological Survey, page 257 ff.

The economic importance of coal mining to the state is illustrated by the fact that in 1902 the 3,931 wage-earners employed received $3,220,263 in wages, a sum equal to 16.9 per cent of the wages paid to all the wage-earners in the manufacturing industries in the state in 1900. Of all the industries reported in the census of manufactures in 1900, only the lumber and timber industry paid a larger sum to wage-earners than the amount reported by coal mining in 1902.

Gold and silver.—The discovery of gold[1] in 1848 did much to attract settlers to Washington. Gold is commonly found in the state associated with iron pyrite, arsenopyrite, chalcopyrite, sphalerite, and galena,[2] the localities of occurrence being chiefly in Chelan, Ferry, Kittitas, Okanogan, Snohomish, Spokane, Stevens, Wallawalla, and Whitman counties.

Silver ores, principally galena,[3] pyrite, and ruby silver in slate, are widespread in their occurrence, being often found in the same veins with gold and copper. In Cedar canyon[2] and some other districts, native silver is also found.

The following table, compiled from reports of the Director of the Mint, shows the annual production of gold and silver from 1891 to 1902:

TABLE 5.—*Annual production of gold and silver: 1891 to 1902.*

[Reports of the Director of the Mint.]

YEAR.	Gold (fine ounces).	Silver (fine ounces).	YEAR.	Gold (fine ounces).	Silver (fine ounces).
1891	16,206	165,000	1897	20,312	106,900
1892	18,071	165,700	1898	37,065	254,400
1893	10,744	152,700	1899	33,156	256,000
1894	11,260	9,683	1900	34,743	224,500
1895	16,980	122,700	1901	28,082	344,400
1896	19,626	274,900	1902	13,166	619,000

As shown by Table 5, the production of precious metals in Washington has fluctuated considerably during the last decade. Extensive development operations during 1902 indicate an unusual interest in the many gold and silver deposits of the state.

Limestones and dolomites.—Extensive deposits of limestone are found in many parts of the state, but thus far only those in the vicinity of large towns or along railroads or boat lines have been developed. Limestone production is third among the important mineral industries of Washington, and the principal quarrying localities are in the northern and northwestern parts of the state.

The limestone quarried in the state has been utilized chiefly in lime burning, and has never been used to any considerable extent as a building material. The production has decreased during the last three years.

Siliceous crystalline rocks.—The siliceous crystalline rocks were second to limestone among the quarry products of the state in 1902, with a product valued at $147,273, or 32.5 per cent of the entire stone production of the state. The principal quarrying localities of this class of rocks are in the region adjacent to Puget sound, although considerable activity was reported in the extreme eastern portion of the state.

A large increase in production is shown for 1902, the value being more than that for the four previous years combined. This increase was principally in rip-rap and rubble, although the reports showed a gain in the use of siliceous crystalline rocks for all purposes.

Marble.—The marble quarried in Washington is of a serpentinous character, and is found principally in the eastern part of the state in Adams and Stevens counties. It is necessarily extracted in small blocks on account of its seamed markings. The production in 1902 was largely utilized for building purposes and interior decorations.

There was a large increase in the production of 1902 over former years, especially in the output of rough and building marble.

Sandstones and quartzites.—The principal occurrences of sandstones in Washington are found in the extreme northwestern part of the state in San Juan and Whatcom counties, and the production has decreased materially as compared with previous years.

All other minerals.—Clay deposits occurring chiefly as glacial clays, residual clays, and clay shales are found, and a small production was reported from the northeastern part of the state, but no extensive mining of these was done during the year.

The prevailing mineralogical character of the copper ore mined in this state is copper glance passing into chalcopyrite, and it is found in fissure veins with granite. The state's production in 1902 was confined to the output of one establishment.

The utilization of molybdenum in the preparation of steel has caused an increased demand for this mineral. It is also used in the manufacture of chemical reagents, principally ammonium molybdate, and in the preparation of "blue carmine" for porcelain coloring.[4] The molybdenite in this state occurs in association with gold, silver, and copper ore, and all the production was reported by one company.

WEST VIRGINIA.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells in the state of West Virginia for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Petroleum.	Natural gas.	Limestones and dolomites.	Sandstones and quartzites.	All other minerals.[1]
Number of mines, quarries, and wells	14,874	522	13,109	949	174	110	10
Number of operators	5,192	406	4,446	63	167	100	10
Salaried officials, clerks, etc.:							
Number	2,614	1,987	328	221	31	38	9
Salaries	$2,443,150	$1,766,448	$399,207	$225,501	$27,259	$18,965	$5,770
Wage-earners:							
Average number	30,002	23,914	3,800	634	1,068	453	133
Wages	$17,469,826	$13,524,429	$2,773,312	$410,845	$426,401	$272,123	$62,716
Contract work	$5,194,279	$23,092	$4,176,647	$994,540			
Miscellaneous expenses	$7,468,346	$2,087,528	$4,523,499	$822,639	$8,144	$17,533	$9,003
Cost of supplies and materials	$8,519,767	$2,327,377	$4,564,908	$1,495,069	$78,146	$28,500	$25,767
Value of product	$48,378,414	$24,748,658	$17,040,317	$5,390,181	$616,366	$423,532	$159,360

[1] Includes operators as follows: Cement, 1; clay, 4; grindstones and pulpstones, 2; iron ore, 1; silica sand, 2.

The extensive coal deposits in the state are almost inexhaustible, coal being found in all but three counties, and the annual production has steadily increased until in 1902 West Virginia ranked fourth among the coal producing states. The oil production is large and the state has within its borders the largest single producing oil field in the world. Natural gas wells are numerous and productive. Most excellent building stones abound throughout the state, and the white sand near Berkeley Springs, in Morgan county, is of exceptional purity. In several places in the state good grits are found for making grindstones. One of the most widespread of all the natural resources of the state is its clay. Iron ore is known to abound in many counties.[1] The manufacture of natural rock cement has been going on for many years.[2]

The following minerals found in the state were not mined or quarried in commercial quantities in 1902: Grahamite, manganese ore, and strontium ore. The celebrated grahamite deposits of Ritchie county, although once mined extensively, have been abandoned for over twenty-five years.[3]

In addition to the active mines, quarries, and wells shown in the foregoing table, development work, confined to bituminous coal, natural gas, and silica sand was reported by 13 operators in 23 mines, quarries, and wells; these gave employment during 1902 to 51 wage-earners, and paid $26,645 in wages. The 14 salaried officials, clerks, etc., received $7,731. The cost of work done by contract was $45,315; the miscellaneous expenses were $6,303, and the cost of supplies and materials amounted to $73,437.

Table 2 shows the value of the products of manufactures, based primarily upon minerals mined and quarried, and also the value of all products manufactured in the state as reported at the census of 1900.

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$74,838,330
Based upon products of mines or quarries:		
Chemicals and allied products	$827,560	
Clay, glass, and stone products	3,934,849	
Iron and steel and their products	20,407,336	
Metals and metal products, other than iron and steel	760,433	
Miscellaneous industries	5,015,645	
		30,945,823
All other		43,892,507

The value of the manufactured products, based primarily upon minerals mined and quarried, was $30,945,823, or 41.4 per cent of the total for all manufactures, as shown in the foregoing table. The total value of products of mines, quarries, and wells of West Virginia in 1902 and manufactures in 1900 amounted to

[1] The Mountain State, by George W. Summers, page 41.

[3] Ibid., Twenty-second Annual Report, 1900–1901, Part I, page 233.

30223—04——22

$123,216,744. Of this amount, manufactures contributed 60.7 per cent, and mines and quarries 39.3 per cent.

In 1900, according to the Twelfth Census reports, 33,272 wage-earners were employed in manufacturing, and the wages paid them during the same year amounted to $12,969,237. The operators of the 14,874 productive mines, quarries, and wells in 1902 employed 30,002 wage-earners, and paid them $17,469,826 in wages. Manufactures and mining together gave employment during the year to 63,274 wage-earners, and paid $30,439,063 in wages. Manufactures, therefore, gave employment to 52.6 per cent of the wage-earners, and paid 42.6 per cent of the wages, while mines, quarries, and wells furnished employment to 47.4 per cent of the wage-earners, and paid 57.4 per cent of the wages.

The following table shows the value of the annual production of the leading minerals of the state from 1890 to 1902:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Petroleum.	Natural gas.	Limestones and dolomites.	Sandstones and quartzites.
1890	$6,208,128	$501,198	$5,400	$93,856	$140,687
1891	7,359,816	1,612,826	35,000	85,000	90,000
1892	7,852,114	2,119,901	500	85,000	85,000
1893	8,251,170	5,425,522	123,000	19,184	46,135
1894	8,706,808	7,221,717	395,000	43,773	63,865
1895	7,710,575	11,038,770	100,000	42,892	40,000
1896	8,336,685	11,829,618	640,000	59,113	24,693
1897	8,987,393	10,310,178	912,528	61,546	47,288
1898	10,131,264	12,426,359	1,334,023	56,167	14,381
1899	12,053,268	18,014,766	2,335,864	58,802	33,860
1900	18,416,871	21,922,702	2,959,032	53,701	72,438
1901	20,848,184	17,172,724	3,954,472	447,049	103,010
1902	24,748,658	17,040,317	5,390,181	616,366	423,532

Coal.—The coal deposits of West Virginia, underlying some 17,280 square miles of the state's area,[1] belong to the great Appalachian coal field, and have almost the largest expanse of continuous coal measures in the world.[2] In all but 4 of the 55 counties of the state bituminous coal has been found.[3]

The advantages of the state in coal production lie in the facts that a great number of the seams found are accessible above water level, and that the coals are of various compositions adapted to the requirements of trade. The fat coking, gassy bituminous, the hard and valuable splint, and the rich and oily cannel coal are found in great purity and made easily accessible through the agency of running water, which has exposed the seams in thousands of places. This fact, added to their size, permits, as a general rule, the mining of coal in West Virginia to be carried on at less cost, and with more economy, under corresponding labor rates, than is possible in any other part of the Allegheny coal fields.[4]

[1] United States Geological Survey, "Mineral Resources of the United States," 1902, page 293.
[2] Resources of West Virginia, by Maury and Fontaine, page 162.
[3] The Mountain State, page 11.
[4] Resources of West Virginia, page 215.

The presence of coal in West Virginia was known to the earliest settlers, and shipments were made from the Cumberland-Piedmont district of Maryland and West Virginia as early as 1842, but until 1855 all the shipments were from Maryland.[5] In 1863 a few small coal mines produced some coal for domestic consumption,[6] and in 1864 the first splint coal was mined at Coalburg, in Kanawha county.[7] During the past twenty-three years the increase in the coal production of West Virginia has averaged 1,000,000 tons a year.

The principal coal producing regions of the state may be divided into four districts, which include the more important coal producing counties. These during 1902 produced nearly 90 per cent of the output of the state. The two northern districts are known as the Fairmont, or Upper Monongahela district, and the Elk Garden, or Upper Potomac district. The two southern districts are the Pocahontas, or Flat Top district, and the New and Kanawha river district. The most important district from the productive point of view is the New and Kanawha river district, which includes the counties of Fayette, Kanawha, Raleigh, and Putnam.[8]

In 1902 coal was mined in 29 counties, among which McDowell ranked first with a production of 5,459,655 tons, Fayette second with 4,775,112 tons, and Marion third with 3,397,194 tons. The total production in 1902 was 24,570,826 tons, an increase of 502,424 tons over 1901. The greatest increase was shown in McDowell county. Fayette county showed a decrease of 1,277,277 tons, due to the strikes in 1902.

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of coal in West Virginia from 1863 to 1902:

TABLE 4.—*Annual production of coal, bituminous: 1863 to 1902.*

spring, and the oil connected therewith, located in the Kanawha valley.[1] Prior to the Civil War the discovery of oil in shallow wells near Parkersburg, in the Burning Springs region in the Little Kanawha valley, caused the most intense excitement, scarcely equaled by that in California over the discovery of gold. Towns sprang into existence, derricks were erected, and oil wells were bored, but the war broke up the oil excitement, the derricks and machinery were destroyed, and for a time, the business was at a standstill.[2] After the close of the Civil War, in 1865, interest in the petroleum in the state was revived and the industry instead of being entirely speculative was put on a legitimate business basis. As a consequence oil development became more scientific and operations were commenced almost simultaneously at Burning Springs, Oil Rock, California House, Volcano, Sandhill, and Horseneck. It is estimated that before 1876 not less than 3,000,000 barrels, valued at $20,000,000, had been produced in these districts.[3]

The following table, compiled from the reports of the United States Geological Survey, shows the annual production of petroleum in West Virginia from 1876 to 1902:

TABLE 5.—*Annual production of petroleum: 1876 to 1902.*

1878	180,000	1893	8,445,412
1879	180,000	1894	8,577,624
1880	179,000	1895	8,120,125
1881	151,000	1896	10,019,770
1882	128,000	1897	13,090,045
1883	126,000	1898	13,615,101
1884	90,000	1899	13,910,630
1885	91,000	1900	16,195,675
1886	102,000	1901	14,177,126
1887	145,000	1902	13,513,345

The modern development of the oil interests of the state dates from 1889. That year marked the opening of the Dolls Run, Eureka, and Mannington oil pools,[4] and from that time until 1900 there was an almost steady increase in the production. In 1900 the output of the oil wells of the state was 16,195,675 barrels.

Although oil had been developed in Pennsylvania long before 1865, it was in West Virginia that the means of transporting it to market in the manner now recognized to be cheap, safe, and expeditious, were first furnished.[5]

In 1902 the production of petroleum in West Virginia amounted to 13,513,345 barrels, a decrease of 663,781 barrels from the product of the preceding year. The 1902 output was valued at $17,040,317. The state ranked second among the oil producing states and territories in 1902, producing 15.1 per cent of the entire output of the United States.

Natural gas.—It is quite probable that the burning springs of West Virginia had attracted the attention of the Indians long before the advent of the white man in this region. One of the earliest records of these natural gas vents was made by George Washington in 1775, when he described a "burning spring" on the Kanawha river, 9 miles above Charleston. This was preempted along with other lands and given to him for military services by the state of Virginia, and he deeded it, together with a square acre of ground, to the public.[6]

The first natural gas field to be developed and put into practical use was that near Wellsburg, Brooke county. Natural gas was first used for manufacturing purposes in West Virginia in the Kanawha valley thirty years before it was used for that purpose in Pennsylvania.[7]

In 1902 West Virginia ranked third among the states in the production of natural gas. Large areas in Lewis, Harrison, Marion, Monongalia, and Wetzel counties were discovered and developed between 1900 and 1902. More or less natural gas has been developed in Tyler, Ritchie, Doddridge, Marshall, Wood, Wirt, Roane, Calhoun, Boone, Mingo, Kanawha, Logan, and Gilmer counties.[8]

Since 1895 there has been a notable yearly increase in production of natural gas. In 1902 the value of the production was $5,390,181, an increase of $1,435,709, or 36.3 per cent as compared with 1901.

Limestones and dolomites.—The value of the output of the 174 quarries productive in 1902 amounted to $616,366, an increase of $169,317 over the product of 1901. Jefferson county ranked first among the 11 counties in value of product, but Preston county ranked first in number of quarries. The value of the blast furnace flux produced in the state in 1902 was $268,059, or 43.5 per cent of the value of all limestone.

Sandstones and quartzites.—Among the beds of the conglomerate coal measures, sandstones of almost any size and texture can be quarried. In Monongalia county a beautiful sandstone, of a light buff and dove color, is found which can be dressed readily, and is most suitable for building purposes. In Taylor county occurs the so-called Grafton sandstone of close texture, sharp and clean grit, and gray color. The gray sandstone of Lewis county has few, if any, superiors in the United States in architectural beauty. The sandstones of the Lower Coal Measures on the upper portion of the Kanawha river have furnished materials for locks and dams built by the Government.[9]

Only 10 of the 110 quarries productive in 1902 had an output valued at more than $10,000. The value of the sandstones quarried in the state in 1902 was $423,532, an increase of $320,522 over the value for 1901. Mercer

[9] Resources of West Virginia, pages 315 and 316.

ranked first among the counties in the state in the value of its sandstones quarried in 1902.

All other minerals.—Natural rock cement was made near Shepherdstown, Jefferson county, as early as 1825.[1] The industry was not followed continuously in this locality, but about 1870 a new plant was erected, and for more than thirty years a superior brand of natural rock cement was produced.[2] A single plant reported production during 1902.

Quantities of good potter's and fire clay are found in the state, and in 1902 West Virginia ranked fourth among the states in the value of its pottery products, which amounted to $1,166,464, and ninth in the value of all its products of clay, which reached $2,518,544. The value of the clay production of the state was $43,266.

Good grits for grindstones are found in many counties in the state, and a part of the well-known ledge of stone appearing in Ohio across the river from Parkersburg is found in Wood county.[3] In 1902 Jackson and Wood were the only counties from which grindstones were reported; the value was $22,347.

Iron ore is found in the coal hills, the best being around Laurel hills and at Beaver Lick mountain; but the enormous beds of ore in the state have been as yet only slightly developed.[4] At various times, before and since the organization of the state, iron has been made from West Virginia ores, which, in every instance, produced iron of an excellent quality.[5] Only one iron mine was operated in the state in 1902.

Near Berkeley Springs, in Morgan county, is a ridge of sandstone, which, when crushed, yields a beautiful white sand of exceptional purity. It is about the best sand found in the United States, and large quantities of it have been shipped for glassmaking.[3] Sand for other uses is obtained in Marion, Hampshire, Randolph, and Monongalia counties.[6] The output of sand in the state for 1902 was 107,520 short tons, of which 74,720 tons were glass sand. The value of all sand was $121,540, while that of the glass sand was $99,340.

WISCONSIN.

Table 1 is a summary of the statistics for the productive mines and quarries in the state of Wisconsin for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Iron ore.	Limestones and dolomites.	Lead and zinc ore.	Siliceous crystalline rocks.	Sandstones and quartzites.	All other minerals.[1]
Number of mines or quarries	411	16	216	90	18	62	9
Number of operators	392	10	207	90	15	62	8
Salaried officials, clerks, etc.:							
Number	275	83	82	50	30	13	17
Salaries	$232,758	$85,262	$58,353	$26,202	$31,284	$9,129	$22,528
Wage-earners:							
Average number	3,583	1,361	1,062	417	391	199	153
Wages	$1,987,565	$837,661	$539,169	$192,209	$236,495	$109,066	$72,965
Contract work	$3,758	$2,750		$1,008			
Miscellaneous expenses	$427,847	$247,149	$47,052	$54,534	$26,211	$3,632	$49,269
Cost of supplies and materials	$804,142	$375,959	$290,150	$56,774	$35,409	$17,169	$28,681
Value of product	$4,427,813	$1,800,864	$1,351,058	$473,652	$369,137	$207,086	$226,016

[1] Includes operators as follows: Cement, 2; clay, 3; copper ore, 1; graphite, 1 (2 mines); mineral pigments, crude, 1.

Wisconsin has valuable iron ore deposits along the borders of Lake Superior in the north, the output of which is yearly increasing, as well as extensive lead and zinc ore mines which have been operated for many years in the Galena-Dubuque region in the southwestern part of the state. Large and valuable areas of building stones are found in many parts of the state, and along the shore of Lake Michigan there are large beds of clay. Flint also is found, but was not mined in commercial quantities in 1902.

The relative importance of manufacturing industries closely allied to or based upon the mining industry, using as their raw material the product of the mine or quarry, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures		$360,818,942
Based upon products of mines or quarries:		
Chemicals and allied products	$1,135,963	
Clay, glass, and stone products	5,159,062	
Iron and steel and their products	36,300,640	
Metals and metal products, other than iron and steel	6,066,962	
Miscellaneous industries	11,808,224	
		60,470,851
All other		300,348,091

The total value of the products of manufactures, based primarily upon minerals mined or quarried, was $60,470,851, or 16.8 per cent of the value of all manufactured products. The value of the output of the mines and quarries in Wisconsin in 1902 was $4,427,813, or 1.2 per cent of the total value of the product of manufacturing and mining industries of the state.

The average number of wage-earners employed in manufacturing establishments in 1900 was 142,076, and the total wages paid amounted to $58,407,597. The corresponding figures for the mines and quarries of Wisconsin in 1902 were 3,583 wage-earners and $1,987,565 paid in wages. It appears that of the number of wage-earners engaged in the two industries during the year, 98 per cent were employed in manufacturing establishments and received 97 per cent of the wages, while 2 per cent of the wage-earners were engaged in mining and were paid 3 per cent of the wages.

The following table shows, for the years from 1890 to 1902, the value of the annual production of the principal minerals, with the exception of lead and zinc for which values can not be obtained:

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Iron ore.	Limestones and dolomites.	Siliceous crystalline rocks.	Sandstones and quartzites.
1890	[1]	$813,963	$266,095	$183,958
1891	[1]	675,000	406,000	417,000
1892	$1,428,921	675,000	400,000	400,000
1893	584,094	543,283	133,220	92,193
1894	320,518	798,406	166,098	94,888
1895	633,165	750,000	80,761	78,000
1896	1,071,511	552,921	126,639	65,017
1897	703,770	641,232	126,134	33,620
1898	687,913	698,454	175,867	80,341
1899	837,766	826,486	270,538	132,901
1900	2,081,272	989,685	407,711	81,571
1901	1,564,173	1,225,448	389,953	90,425
1902	1,800,864	1,351,058	369,127	207,086

[1] Value not reported.

Iron ore.—Although the existence of iron ore, similar to the Michigan ore, occurring in Wisconsin along Lake Superior, was known early in the last century, nothing of any consequence was done toward developing the deposits until about 1877, when work was begun in Florence county, and in 1882, 276,017 tons were shipped from that county. The greatest development of the iron ore resources of the state has occurred since 1884 in the Gogebic district in Ashland and Iron counties.[1] Iron ore of the red hematite variety from the Iron Ridge, in Dodge county, was probably mined to some extent as early as 1854, reference being made in that year to its quality and abundance.[2] In 1902 the state produced 783,996 long tons. The greatest amount was mined in Iron county, which produced about 79 per cent of the total. The production in the state from 1889 to 1902 is shown in the following table:

TABLE 4.—*Annual production of iron ore: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Long tons.	YEAR.	Long tons.
1889	837,399	1896	607,405
1890	948,965	1897	554,155
1891	589,481	1898	509,645
1892	790,179	1899	579,798
1893	439,429	1900	746,105
1894	347,501	1901	738,868
1895	649,351	1902	783,996

Limestones and dolomites.—Limestone underlies a large part of Wisconsin, the beds extending in a broad belt through the eastern, southern, and western portions of the state. The suitability of the stone for building purposes varies greatly, not only in the different formations, but also in the different beds of the same formation, and the color of the stone ranges from buff, or straw-yellow, to dark bluish gray.[3]

The earliest recorded quarry in the state was opened at Genesee, Waukesha county, in 1848, and this quarry was operated continuously until 1872, since which time it has been worked only at intervals. The Wauwatosa quarries, near Milwaukee, were opened in 1855, and one year later the quarry near Bridgeport was opened.[4] Previous to 1880, however, with a single exception, no product of the quarries had been exported from the state.[5]

Wisconsin ranked seventh in 1902 among the limestone producing states. The value of its production was $1,351,058, of which $296,998 was the value of the building stone, which comes principally from the quarries in Brown, Door, Milwaukee, Rock, and Waukesha counties. The largest quarries were in Calumet, Door, Fond du Lac, Manitowoc, Racine, and Waukesha counties.

Lead and zinc ore.—The lead mines of the upper Mississippi valley district, comprising Grant, Lafayette, and Iowa counties in Wisconsin; Jo Daviess county in Illinois; and Dubuque county in Iowa, seem to have been discovered by Nicholas Perrott about 1692. This metal was also noticed by Le Sueur in 1700, and by John Carver in 1766. The first mining in this district was done by Julien Dubuque in 1788 on the site of the present city of Dubuque, Iowa, but it was not until about 1830 that lead mining became general in southwestern Wisconsin. From that time until today mining has been continuous in the state.[6] About 1860 zinc ore was first mined, the earlier work having been entirely devoted to lead mining; now, however, this district has become more important as a source of supply of zinc than of lead ore. The ores mined are galena, smithsonite, and sphalerite, the latter being the most important.[6]

In 1902 the total production of lead and zinc ore in Wisconsin amounted to 21,999 short tons, having a value of $473,652. Of this production only 2,623 tons were lead ores. Lafayette county had a production of 9,156 short tons, the greater part of which was sphalerite. Of the 90 mines operated in 1902, 27 mined lead ore only, 23 mined zinc ore only, and 40 mined both lead and zinc ore.

Siliceous crystalline rocks.—Although about one-third of the entire area of Wisconsin is underlaid by the older siliceous crystalline rocks, it has been within the last twenty-five years only that the quarrying of granite has assumed any considerable importance, and even now the annual output is insignificant when compared with that of many other states.[7] For monumental purposes the Wisconsin granites have been selected in preference to granites from other parts of the country, and for structural purposes the quarries can furnish either gray or red granite of any required dimension. For road construction probably no state in the Union is better provided with material. The granites vary in texture from exceedingly fine grained to the coarse grained porphyritic variety, and in color from a brilliant red to a dark gray. The first granite quarry was opened at Granite Heights in Marathon county in 1880.[8] Near Utley, in Green Lake county, there occurs a beautiful stone, almost black in color, with white porphyritic feldspar, which has been quarried to some extent; and near Berlin, in the same county, occur two mounds of compact, dense grayish black to pinkish quartz porphyry or rhyolite, which takes a high polish and seems to be eminently adapted for monumental work.[9]

[8] Wisconsin Geological and Natural History Survey, Bulletin No. IV, pages 89, 90, and 132.
[9] Stones for Building and Decoration, pages 167 and 168.

The 18 quarries operating in 1902 were located in Dodge, Green Lake, Marathon, Marinette, Marquette, Sauk, Waupaca, and Waushara counties, and their output was valued at $369,137.

Sandstones and quartzites.—One of the most widely distributed building stones, and one which furnishes perhaps the greatest variety in color and texture among the sedimentary rocks, is the sandstone of the Potsdam and St. Peter's formation. The Potsdam appears first in the northeast corner of the state and swings in a broad belt around to the southwest and then again northwest. A second smaller belt skirts the south shore of Lake Superior entirely across the state in an east and west direction. The stone from this belt, on account of its color, is commonly known as the Lake Superior brownstone, and was first quarried in 1868 on Bass Island. This stone was quarried in the counties of Ashland, Bayfield, and Douglas, and has been used for structural purposes in many states.[1] The stone quarried from the southern Potsdam area is mostly used locally, the color, texture, durability, and composition of the stone varying greatly in the different beds. The so-called St. Peter's sandstone is found in a comparatively narrow strip extending from the Menominee river, in the northeastern part of the state, south as far as the state line, thence west to the Mississippi river. The stone is brown, red, yellow, or nearly white in color, and as a rule is coarse and rather friable.[1]

Based on the value of product, Sauk ranked first among the sandstone producing counties of Wisconsin, Dunn county second, and Bayfield third. Only 6 of the 23 counties in which sandstone is quarried had a value of output in excess of $10,000. The value of the sandstone quarried in the state in 1902 was $207,086.

All other minerals.—In 1875, at Whitefish Bay, Milwaukee county, the first cement mill in the state was erected, and with scarcely any interruption this plant has been a steady producer of an excellent quality of natural rock cement. A second plant was erected near the first in 1890. Based on the value of the production, Wisconsin ranked fourth among states producing natural rock cement.

Stratified beds of clay, from which over 50,000,000 brick are made annually, are found along the shore of Lake Michigan. Although the clay usually is red the bricks are cream colored, and Milwaukee derives its name of "The Cream City" from the fact that this brick has been used so extensively in its buildings.[2] The value of the clay produced in Wisconsin in 1902 was $23,178, and the value of the brick and tile made from it was $1,014,373.[3]

There are copper ores in the zinc and lead district of southwestern Wisconsin, and some crude attempts at copper mining have been made. By far the most important recent development, however, has been in Douglas county, in the northern part of the state.[4]

Some graphite was produced in Portage county in 1902, and some metallic paints were made from a certain hematite iron ore found in Dodge county, but no figures can be shown for either of these minerals without disclosing individual operations.

WYOMING.

Table 1 is a summary of the statistics for the productive mines, quarries, and wells of the state of Wyoming for 1902.

TABLE 1.—SUMMARY: 1902.

	Total.	Coal, bituminous.	Sandstones and quartzites.	Limestones and dolomites.	Gold and silver.	All other minerals.[1]
Number of mines, quarries, and wells	74	36	12	3	4	19
Number of operators	50	22	12	3	4	9
Salaried officials, clerks, etc.:						
Number	153	125	3	.....	4	21
Salaries	$188,616	$159,153	$2,038	.....	$3,245	$24,180
Wage-earners:						
Average number	4,486	4,197	74	7	25	183
Wages	$3,432,059	$3,207,545	$58,897	$5,640	$24,570	$135,407
Contract work	$15,547	$12,747	.....	.....	$300	$2,500
Miscellaneous expenses	$280,602	$224,947	$2,291	$2	$160	$53,202
Cost of supplies and materials	$818,496	$669,328	$4,337	$225	$11,139	$133,467
Value of product	$5,684,286	$5,236,339	$90,691	$6,340	$4,923	$345,993

[1] Includes operators as follows: Copper ore, 1; graphite (1 mine, operator reported in South Dakota); grindstones and pulpstones (operator reported under sandstones and quartzites); gypsum, 2 (3 quarries); iron ore, 1; petroleum, 2 (13 wells); precious stones, 3 (no mines).

Wyoming is excelled by few states in the variety and amount of its mineral resources.[1] Although greatly hindered in the development of its mines and quarries because of the lack of capital and means of transportation, its product in 1902 was valued at $5,684,286. In the value of its mineral products the state was twenty-seventh in rank; almost the entire mineral production was from its mines of coal, in the output of which mineral the state ranked fourteenth.

The rocks included in the group "sandstones and quartzites," occur in almost inexhaustible beds, and are equal to those of any other state in point of beauty and durability.[2]

Limestones and dolomites are of wide occurrence and were quarried to a limited extent in 1902.

Gold and silver mining, which was an important factor in the early development of the state, has decreased in importance, until in 1902 the product amounted to only $4,923.

Other minerals produced commercially in 1902 were copper ore, graphite, grindstones and pulpstones, gypsum, iron ore, petroleum, and precious stones.

Arsenic, asbestos, glass sand, granite, kaolin, and fire clay, magnesium, marble, mica, platinum, vein and stream tin, and volcanic ash are of known occurrence in the state, but were not mined on a commercial scale in 1902.[3]

[1] The State of Wyoming, by Fenimore Chatterton, pages 9 and 13.
[2] Ibid., page 17.
[3] Ibid., page 13 ff.

Development work confined to gold and silver and petroleum was reported by 87 operators in 1902. They paid out $405,285 for salaries and wages, $86,204 for contract work, $35,120 for expenses of a miscellaneous character, and $140,754 for supplies and materials.

Certain manufacturing industries are closely allied to or based upon the mining industry, using as raw material the products of mines and quarries. The relative importance of these branches of manufacture, as indicated by the value of their products, is shown in the following table:

TABLE 2.—*Manufactures based primarily upon the products of mines and quarries: 1900.*

INDUSTRY.	Value of product.	
All manufactures	.....	$4,301,240
Based upon products of mines or quarries:		
Clay, glass, and stone products	$43,675	
Iron and steel and their products	332,175	
Metals and metal products, other than iron and steel	43,102	
Miscellaneous industries	225,662	
		644,614
All other	.....	3,656,626

The total value of product of these manufacturing industries based on mining was, as shown by Table 2, $644,614, or 15 per cent of the product of all manufactures in the state in 1900.

The number of wage-earners employed in manufactures in 1900 was 2,241, and they received $1,386,140 in wages. In 1902, 4,486 wage-earners were employed

in mines and quarries, and they were paid $3,432,059 in wages. By combining the figures for these two branches of industry it is shown that mines and quarries furnished employment to 66.7 per cent of the wage-earners, and paid 71.2 per cent of the wages, while there were employed in manufactures 33.3 per cent of the wage-earners, who were paid 28.8 per cent of the wages.

Table 3, compiled from the reports of the United States Geological Survey, shows the value of the annual production of the principal minerals from 1890 to 1902.

TABLE 3.—*Value of annual production of principal minerals: 1890 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Coal, bituminous.	Sandstones and quartzites.	Gold and silver.[1]
1890	$3,183,669	$16,760	(2)
1891	3,555,275	25,000	(2)
1892	3,168,776	15,000	(2)
1893	3,290,904	100	(2)
1894	3,170,392	4,000	(2)
1895	2,977,901	10,000	(2)

[2] Not reported separately.
[3] Silver at commercial value.
[4] Census figures, except for gold and silver.

Coal, bituminous.—The production of coal on a commercial scale in Wyoming began in 1869.[1] The first mine was opened at a point about 3 miles from Evanston, in Uinta county, soon after the construction of the transcontinental railway.

The coal fields of Wyoming cover an area of more than 20,000 square miles; they have been known since 1850, but remained undeveloped until 1868 because of the lack of transportation facilities and market.[2] Since that time coal mining has developed into the leading branch of mineral industry in the state, and the known area of coal deposits has been extended through successive discoveries until it includes every county in the state; some of the veins vary in thickness up to 75 feet. The most common variety is a pure lignite, though in certain localities a good coking coal is mined. In 1887 a semianthracite coal was discovered in Johnson county.[3]

The best grades are low in ash and sulphur, and are excellent for steam making, domestic purposes, and the manufacture of gas. During the early development of the industry, almost the entire product was sold to the railway companies,[4] but in later years their consumption has amounted approximately to one-third of the production.[5]

1877	342,853	1890	1,870,366		

In 1902 the reports from 11 of the 13 counties showed the mining of coal. Sweetwater county ranked first, with a product of 1,595,340 tons, followed by Uinta, with 1,595,333; Carbon, with 382,207; and Converse, with 72,329 tons. The state's production in 1902 shows a decrease from that of 1901 of 55,883 tons, Carbon and Sweetwater counties showing the greatest loss. The statistics for Uinta county show an increase of 156,186 tons for the year.

Sandstones and quartzites.—A large amount of the product of the sandstone quarries in Carbon county is shipped to Colorado, Nebraska, and Utah. The capitol at Cheyenne and the state penitentiary were built of this stone. The Iron mountain quarries in Laramie county produce a white stone that is much used for building purposes. The Carnegie Library and Federal building at Cheyenne were constructed from this material.[6]

In 1902 sandstones and quartzites were quarried in Albany, Carbon, Crook, Laramie, and Uinta counties. Of the total production, $90,691, that sold for building purposes amounted to $40,451, and that for rubble to $10,096.

Limestones and dolomites.—There are several exposures of a thick limestone formation near Lava creek and in the valley of the East Fork of the Yellowstone river. Compact crystalline limestone also occurs near the summit of the Owl creek range of mountains, and in the Wind river range there are numerous strata resembling the Quebec and Niagara limestones.[7]

The only quarries reported in 1902 were in Albany county, and their product amounted to $6,340. Of this amount, $2,250 was the value of stone used for lime making and $4,000 the value used for blast furnace flux.

Gold and silver.—Though the Laramie trail, one of the principal highways to the Pacific coast, was traversed by many caravans of Mormons on their way to Deseret, Utah, and by thousands of prospectors going

[6] The State of Wyoming, page 17.
[7] Reconnaissance of Wyoming, by William A. Jones, pages 111 and 112.

to the gold fields of California, the occurrence of gold in Wyoming was not discovered until 1867. In that year the placer mines on the Sweetwater river were found, and for several years produced rich results. Placer and quartz mines have been discovered in almost every county in the state.[1] The annual production of gold and silver in the state since 1867 has ranged in value from $25,000 to $125,000.[2]

All other minerals.—Copper, in the form of glance, pyrites, silicate, green carbonate, and red oxide, occurs in Laramie, Carbon, Albany, and Crook counties.[3]

Veins of graphite occur at French creek, Plumbago canyon, and Halleck canyon in Albany county, and in the Indian Grove mountains in Carbon county. The veins are large and easily accessible and contain from 40 to 60 per cent of carbon.[4]

The Triassic formation exposed along the eastern side of the Laramie plains contains a large percentage of gypsum, one stratum near the bottom of the formation being of considerable thickness. The Laramie bed, known locally as a deposit of gypsite, has an average depth of 9 feet, and the mineral needs only to be calcined to prepare it for the market. The manufacture of plaster of Paris and stucco has been carried on at Red Buttes since 1889.[5]

The occurrence of iron ore has been known for some time at a point 2½ miles north of Rawlins station. Two mines were opened here in 1871 and worked until 1877. Since that time only a few tons have been mined in this region and these have been used for the manufacture of mineral paints.[6] Hematite ore has been discovered since in Crook, Uinta, Johnson, Fremont, Bighorn, Albany, and Sheridan counties. Besides these hematites, beds of clay ironstone have been found in the Cretaceous rocks and magnetites in the Laramie mountains.[7] Iron mountain, in Laramie county, 52 miles north of Cheyenne, is a mass of red hematite 7 miles long,[1] and Bradleys peak in Carbon county has been called a mountain of iron since it contains not less than 1,500,000,000 tons of iron ore.[7]

About a quarter of a century prior to the great oil excitement in Pennsylvania, Bonneville announced the discovery of oil in Wyoming. Little attention seems to have been paid to his announcement because the territorial geologist, as late as 1890, stated that the first discovery had been made only twenty-five years before. Certainly from 1869 to 1880, little or no attention was paid to oil in the state. In Crook county a company collected oil from the springs and sold it to miners until the advent of the railway, which could bring eastern lubricating oil cheaper than it could be brought in by team from points in Wyoming.

The oil industry of the state was placed on a profitable basis in 1894, when a company at Casper completed its wells in the Salt Creek basin. Because of the necessary haul by wagon and the high freight rates, progress in the development of this industry has been necessarily slow. There are now 19 known fields located in Bighorn, Converse, Crook, Fremont, Natrona, Uinta, and Weston counties.[8] The oil is stored in sandstone, magnesium, limestone, and conglomerate. It occurs in all possible grades, containing in some cases as high as 40 per cent of illuminating oil, and ranges in color from honey-yellow to jet-black.[9]

The semiprecious stones are found in abundance, quartz crystals, agates, jaspers, moss agates, garnets, and beryls being the most important ones. The moss agates found here are the best in the world.[10] No mines were in operation in 1902, though three operators reported the finding of precious stones in surface workings.

[1] Includes electric and other horsepower "supplied by other establishments," but does not include horsepower of electric motors owned.
[2] Long tons.
[3] Includes 132,330 short tons of lead ore and 491,332 short tons of zinc ore.
[4] Quicksilver, flasks, 34,291 (76½ pounds each); cinnabar, 11,727 short tons.
[5] Barrels of 42 gallons.
[6] Barrels.
[7] Roofing slate reported, 1,435,168 squares; quantity for other uses not given.
[8] Number of stones.

[9] Includes 2,600 short tons of crude.
[10] Includes 21,870 short tons of crude.
[11] Includes 16,070 short tons of ground.
[12] Includes 3,162 short tons of refined.
[13] Cut or sheet mica, 373,266 pounds; scrap or waste, 1,400 short tons.
[14] Pounds.
[15] Includes operators as follows: Chrome ore, 1; magnesite, 1; molybdenum, 1; nickel and cobalt, 2; rutile, 1.

DETAILED SUMMARY, BY STATES AND TERRITORIES

[1] Long tons.
[2] Includes operators as follows: Bauxite, 1 (3 mines); cement, 1; graphite, 1; marble, 1; sulphur and pyrite, 1.
[3] Includes operators as follows: Fluorspar, 2; lead and zinc ore, 1; precious stones, 46 (1 mine); siliceous crystalline rocks, 1.
[4] Includes operators as follows: Asphaltum and bituminous rock, 1; fuller's earth, 2; gold and silver, 1; manganese ore, 2; marble, 1; mineral pigments, crude, 1; phosphate rock, 1; precious stones, 50 (no mines); slate, 1.
[5] Includes 2 operators in Alaska.
[6] Barrels of 42 gallons.
[7] Quicksilver, 28,972 flasks (76½ pounds each) and 10,427 short tons of cinnabar.
[8] Includes 1 operator in Hawaii.
[9] Includes operators as follows: Cement, 2; chrome ore, 1; gypsum, 1; infusorial earth, tripoli, and pumice, 1; lithium ore, 2; magnesite, 1; mica, 1 (10 mines); mineral pigments, crude, 2; slate, 1; talc and soapstone, 1; sulphur and pyrite, 2.

[10] Includes 100 short tons of lead ore and 1,536 short tons of zinc ore.
[11] Includes operators as follows: Cement, 1; gypsum, 1; natural gas, 3; precious stones, 25 (no mines); tungsten, 3.
[12] Includes 5,207 tons of crude.
[13] Includes 852 tons of crude.
[14] Includes operators as follows: Asbestos, 1; clay, 1; garnet, 2; iron ore, 1 (2 mines); marble, 1; tungsten, 1.
[15] Includes operators as follows: Clay, 2; fuller's earth, 2.

TABLE 3.—DETAILED SUMMARY, STATES AND

	STATE OR TERRITORY AND MINERALS.	Number of mines, quarries, and wells.	Number of operators.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS.					
						Total.		Men 16 years and over.		Boys under 16 years.	
				Number.	Salaries.	Average number.	Wages.	Average number.	Wages.	Average number.	Wages.

[1] Long tons.
[2] Includes operators as follows: Asbestos, 1; cement, 2; graphite, 2; infusorial earth, tripoli, and pumice (operator reported under talc and soapstone); mica, 1; sandstones and quartzites, 1; slate, 1; talc and soapstone, 1; sulphur and pyrite, 1.
[3] Includes operators as follows: Coal, bituminous, 5; copper ore, 1; precious stones, 1; siliceous crystalline rocks, 2.
[4] Barrels.
[5] Includes 792 short tons of lead ore and 2,778 short tons of zinc ore.
[6] Includes 1 operator (2 wells) for petroleum.
[7] Includes operators as follows: Natural gas, 1; petroleum, 2 (13 wells); siliceous crystalline rocks, 1.
[8] Barrels of 42 gallons.

TERRITORIES, BY MINERALS: 1902—Continued.

WAGE-EARNERS—continued.				CONTRACT WORK.		MISCELLANEOUS EXPENSES.				PRODUCT.		
Above ground.		Below ground.										
Average number.	Wages.	Average number.	Wages.	Amount paid.	Number of employees.	Total.	Royalties and rent of mine and mining plant.	Rent of offices, taxes, insurance, interest, and other sundries.	Cost of supplies and materials.	Quantity (short tons).	Value.

[9] Includes operators as follows: Clay, 2; oilstones, whetstones, and scythestones, 5 (6 mines); sulphur and pyrite (operator reported under coal, bituminous).
[10] Includes 186 short tons of lead ore and 375 short tons of zinc ore.
[11] Includes 3,468 short tons of lead ore and 21,642 short tons of zinc ore.
[12] Includes operators as follows: Cement, 2; gypsum, 5 (7 quarries).
[13] Includes operators as follows: Cement, 1 (2 quarries); iron ore, 3; lead and zinc ore, 1; oilstones, whetstones, and scythestones, 1.
[14] Includes operators as follows: Petroleum, 2 (7 wells); sulphur and pyrite, 1.

TABLE 3.—DETAILED SUMMARY, STATES AND

	STATE OR TERRITORY AND MINERALS.	Number of mines, quarries, and wells.	Number of operators.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS.					
				Number.	Salaries.	Total.		Men 16 years and over.		Boys under 16 years.

[1] Includes operators as follows: Feldspar, 5; flint (operator reported under feldspar); mica, 2; precious stones, 13 (no mines).
[2] Barrels.
[3] Includes 1,895 short tons crude.
[4] Includes operators as follows: Feldspar, 2 (3 mines); gold and silver, 1; infusorial earth, tripoli, and pumice, 1; marble, 2; talc and soapstone, 2.
[5] Includes operators as follows: Asbestos, 1; clay, 1; corundum and emery, 1; feldspar (operator reported under flint); flint, 1; graphite, 1; infusorial earth, tripoli, and pumice, 1; iron ore, 1; sulphur and pyrite, 1; talc and soapstone, 1.
[6] Long tons.
[7] Includes operators as follows: Clay, 1; graphite, 2; grindstones and pulpstones (operator reported under sandstones and quartzites); oilstones, whetstones, and scythestones (operator reported under sandstones and quartzites); petroleum, 1 (13 wells).

[8] Includes 2 operators for cement.
[9] Includes 124,537 short tons of lead ore and 240,057 short tons of zinc ore.
[10] Includes operators as follows: Cement, 1; infusorial earth, tripoli, and pumice, 2; mineral pigments, crude, 2; nickel and cobalt, 1; petroleum, 2 (10 wells); sulphur and pyrite, 2.
[11] Includes operators as follows: Corundum and emery, 1; flint, 1; graphite, 1 (8 mines); grindstones and pulpstones (operator reported under sandstones and quartzites); gypsum, 2; iron ore, 3; manganese ore, 1; marble, 1.
[12] Includes operators as follows: Infusorial earth, tripoli, and pumice, 1 (2 quarries); limestones and dolomites, 33; sandstones and quartzites, 1.
[13] Includes operators as follows: Borax, 1; copper ore, 1; gypsum, 1; limestones and dolomites, 1; precious stones, 8 (1 mine); siliceous crystalline rocks, 1; sulphur and pyrite, 1.

TABLE 3.—DETAILED SUMMARY, STATES AND

	STATE OR TERRITORY AND MINERALS.	Number of mines, quarries, and wells.	Number of operators.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS.					
						Total.		Men 16 years and over.		Boys under 16 years.

[1] Includes operators as follows: Infusorial earth, tripoli, and pumice, 1; mica, 2; oilstones, whetstones, and scythestones (2 mines; operator reported in Arkansas); precious stones, 10 (no mines).
[2] Long tons.
[3] Includes operators as follows: Cement, 2; lead and zinc ore, 1; slate, 1; talc and soapstone, 1.
[4] Includes operators as follows: Graphite, 1; iron ore, 1 (2 mines); lead and zinc ore, 1; marble, 2; mica, 1; phosphate rock, 1.
[5] Stones.
[6] Barrels.
[7] Includes 50 tons crude.
[8] Barrels of 42 gallons.
[9] Includes operators as follows: Crystalline quartz, 1; feldspar, 1; flint, 2; infusorial earth, tripoli, and pumice, 1; lead and zinc ore, 1; sulphur and pyrite, 1.

[10] Cut or sheet mica, 303,816 pounds; scrap or waste, 544 short tons.
[11] Pounds.
[12] Includes operators as follows: Buhrstones and millstones (operator reported under siliceous crystalline rocks); clay, 3; coal, bituminous, 1; copper ore, 2; garnet, 1; graphite, 2; iron ore, 3; precious stones, 18 (1 mine); sandstones and quartzites, 2.
[13] Includes operators as follows: Cement, 1; coal, bituminous, 47.
[14] Includes grindstones and pulpstones, valued at $399,726, for which all operating expenses are reported under sandstones and quartzites.
[15] Includes operating expenses of grindstones and pulpstones, valued at $399,726, produced in sandstone quarries.
[16] Includes operators as follows: Gypsum (2 quarries; operator reported in Michigan); oilstones, whetstones, and scythestones, 1; phosphate rock, 1.
[17] Includes operators as follows: Gypsum, 3 (5 quarries); petroleum, 1 (3 wells); sandstones and quartzites, 1.

[1] Includes operators as follows: Borax, 1; copper ore, 2; gypsum, 1; nickel and cobalt, 1; sandstones and quartzites, 1.
[2] Stones.
[3] Barrels.
[4] Long tons.
[5] Includes 4,238 tons crude.
[6] Barrels of 42 gallons.
[7] Includes operators as follows: Crystalline quartz, 1; garnet, 1; graphite, 2; phosphate rock, 1; precious stones, 55 (no mines); talc and soapstone, 2.
[8] Includes operators as follows: Graphite, 1; limestones and dolomites, 2.

[9] Includes operators as follows: Gold and silver, 3; limestones and dolomites, 1; manganese ore, 1; precious stones, 5 (no mines).
[10] 6,000 pounds cut or sheet mica, 205 short tons rough as mined.
[11] Includes operators as follows: Cement, 1; graphite, 2; gypsum, 2; lithium ore, 1; precious stones, 3 (no mines).
[12] Includes operators as follows: Copper ore, 2; fluorspar, 1; gold and silver, 2; mineral pigments, crude, 1; natural gas, 1 (2 wells); petroleum, 1 (7 wells).
[13] Quicksilver, 5,319 flasks (76½ pounds each); cinnabar, 1,300 short tons.
[14] Includes operators as follows: Asphaltum and bituminous rock, 1; cement, 2; gold and silver, 1; gypsum, 2; iron ore, 1 (2 mines).
[15] Includes operators as follows: Asphaltum and bituminous rock, 2; cement, 1; clay, 1; gypsum, 1; iron ore, 4; marble, 2; sulphur and pyrite, 1.

[6] Includes operators as follows: Clay, 1; copper ore, 1; molybdenum, 1.
[7] Barrels of 42 gallons.
[8] Includes operators as follows: Cement, 1; grindstones and pulpstones, 2; iron ore, 1; silica sand, 2.
[9] Includes 2,623 short tons of lead ore and 19,376 short tons of zinc ore.
[10] Includes operators as follows: Cement, 2; copper ore, 1; graphite, 1 (2 mines); mineral pigments, crude, 1.
[11] Includes operators as follows: Copper ore, 1; graphite (1 mine; operator reported in South Dakota); grindstones and pulpstones (operator reported under sandstones and quartzites); gypsum, 2 (3 quarries); iron ore, 1; petroleum, 2 (13 wells); precious stones, 3 (no mines).

REPORTS ON SEPARATE MINERALS

IRON ORE

IRON ORE.

By JOHN BIRKINBINE.

The statistics which are given in this report refer solely to the iron ore mines located in the United States, excluding the insular possessions and Alaska; they show that in the year 1902, 35,567,410 long tons of iron ore were mined in the United States, 25 states and territories contributing to make this total. This includes 13,275 tons of special manganiferous iron ores obtained in Colorado. These ores were included because the labor and wages expended on them could not be segregated from those expended on the iron ores proper. The amount of true iron ore produced was 35,554,135 long tons.

The statistics included in this report do not show fully comparative data for the various census years because the inquiries at the different census periods were not identical. However, such as are shown will aid in a study of past and existing conditions.

Prior to 1880, the number of iron ore mines grew with the pig iron industry, individual blast furnaces depending largely upon mines which were adjacent to the plant or controlled by the same owners. Subsequently, as blast furnaces were enlarged requiring greater amounts of iron ore, it became necessary that several mines should be combined under the same management, or that existing mines should be exploited to a more liberal extent than before.

In Table 1 the statistics for each of the census years 1902, 1889, and 1880 are presented, but a résumé of the data, so far as it could be collated, for 1850, 1860, and 1870 is given, as follows: In 1850 the "number of establishments" was 197; the wage-earners were 2,195, receiving a total of $590,866 in wages; the cost of supplies and materials was $63,651, and the value of the product of the regular mining establishments to which these data refer was $1,217,803; but the amount of iron ore smelted was given as 1,579,309 long tons.

In 1860 the total amount of iron ore mined from 157 regular mining establishments was 908,300 short tons, or 810,982 long tons. These establishments gave employment to 3,177 persons, to whom $901,852 was paid in wages, and $249,699 was the cost of raw material. In addition, many of the large iron works of the country mined their own ore, the quantity thus raised amounting to 2,309,975 short tons, making the total quantity 3,218,275 short tons, or 2,873,460 long tons. While the short ton was not designated as the unit of measure in 1860 or 1870, it was reported in 1880 and presumably was used at prior censuses.

In 1870 there were 420 regular mining establishments, employing 15,022 wage-earners, who received as compensation $6,838,022. The cost of supplies and materials was $1,279,563. The product was 3,395,718 short tons, equivalent to 3,031,891 long tons, valued at $13,204,138. This production does not include the amount raised, between 800,000 and 900,000 tons, by some of the blast furnace operators, so that at a low estimate the production of 1870 reached a total of at least 3,831,891 long tons.

The inquiries for the census years 1902, 1889, and 1880 were more nearly identical than any of the others, and therefore a comparison of these gives results of greater immediate value. The statistics for these periods are summarized in the following table:

TABLE 1.—*Comparative summary: 1880 to 1902.*

	1902	1889	1880
Number of mines	525	592	[1]
Number of operators	332	[1]	[2]805
Salaried officials, clerks, etc.:			
Number	2,405	[3]520	1,253
Salaries	$2,113,230	$529,043	[4]
Wage-earners:			
Average number	38,851	[3]37,707	30,415
Wages	$21,531,792	$13,880,108	[4]$9,538,117
Contract work	$425,292	$1,578,010	[1]
Miscellaneous expenses	$8,257,714	$3,795,509	[1]
Cost of supplies and materials	$9,005,608	$4,998,988	$2,894,011
Product:			
Quantity, long tons	35,567,410	14,518,041	7,120,362
Value	$65,465,321	$33,351,978	$23,156,957

[1] Not reported.
[2] Establishments.
[3] Foremen included as wage-earners.
[4] Salaries included in wages.

The number of mines in 1902 shows an apparent decrease of 67 since 1889, which was caused in part by a difference in the methods followed at the two censuses. In the year 1889 all iron mines were included which were doing exploratory work. In the statistics for 1902, however, only the mines which contributed iron ore are included, 257 which were being prospected,

or in which shafts were being sunk, or which were temporarily idle, being excluded. There have been numerous consolidations of important mines, thus reducing still further the number reported in 1902. In many instances two or three mines which were formerly operated independently have been united, connected with common shafts or slopes, and the ore usually all mined under one management. Thus, the Chapin mine, on the Menominee range in Michigan, combines what were formerly known as the Chapin, Ludington, and Hamilton mines; the Norrie mine, on the Gogebic range in Michigan, embraces the North Norrie, East Norrie, Norrie, and Pabst; and the Cary mine, on the same range in Wisconsin, represents the Cary, West Cary, and Odanah mines. Other similar consolidations in the Lake Superior and Southern districts could be mentioned.

In the 1880 census the number of establishments was reported as 805; this included a number of small operations, especially in the eastern section of the United States, which were afterwards abandoned because improved transportation facilities permitted the utilization of the richer ores of the Lake Superior district where operations on a large scale were possible.

The number of wage-earners and salaried officials was 38,227 in 1889 and 41,256 in 1902, but the compensation paid them increased from $14,409,151 in 1889 to $23,645,022 in 1902. It would appear, therefore, that the proportionate increase in the amount paid was much greater than in the number employed. This is due, in part, to the different methods used in the calculation of the average number of men employed. In 1902 the number of employees in active mines only were considered, and the average number employed during the year was reduced to correspond with the number which would be required at "continuous employment for twelve months to produce the quantity of product reported." Thus, if 200 men were employed at an open cut mine which, owing to climatic conditions, could be operated for only nine months during the year, the average number for the entire year, as determined in 1902, would be 150 instead of 200. The proportionate increase in the amount paid, therefore, is not so much greater than that in the number of employees as it might seem from the statistics.

Moreover, in the 1889 census all of the persons employed at mines which were active, or might again become active, were included. If to the number given for 1902 in Table 1 those employed in the exploitation of mines not yet shipping ore and in mines temporarily idle be added, the total number of persons employed would be increased from 41,256 to 41,551, and the wages from $23,645,022 to $23,822,339. In addition, in 1902, 1,365 men were employed by contractors in active mines and in development work, the contractors receiving $641,460.

In the year 1889 the cost of supplies and materials was $4,998,988, the amount paid in wages and salaries was $14,409,151, contract work cost $1,578,010, and miscellaneous expenses $3,795,509, a total of $24,781,658. In the year 1902 the total wages and salaries were $23,645,022, contract work cost $425,292, supplies and materials $9,005,608, miscellaneous expenses were $8,257,714, a total of $41,333,636.[1]

Table 1 indicates that in 1902 the quantity of ore mined was about five times the product in 1880, but that the value of the ore produced in 1902 was less than three times that of 1880.

The total value at the mines of the 35,567,410 long tons of iron ore produced during the year 1902 was $65,465,321, an average of $1.84 per ton. The value of the 14,518,041 long tons produced in the year 1889 was $33,351,978, or $2.30 per ton. This shows an increase in quantity of 21,049,369 long tons and in value of $32,113,343. Because of the greater use of labor-saving appliances, and other economies, resulting in part from the consolidation of contiguous mines, the average value per ton shows a reduction of 46 cents, or 20 per cent.

In the following statement the average value at the mine per ton of iron ore is presented for the census years from 1860 to 1902, inclusive. The figures for the regular mining establishments are taken for the earlier years, as the difference in total amount would make little change in the average value per ton of product.

CENSUS YEAR.	Average value at the mine per long ton of iron ore.
1860	$2.69
1870	4.35
1880	3.25
1889	2.30
1902	1.84

In the earlier census years the mines were nearer the furnaces, while in the later the ore was carried long distances to points of consumption. This explains, in part, the higher value at the mines in former years.

Development work.—In connection with mining a certain amount of preparatory or exploratory work is always required. In most of the producing mines the labor, cost of supplies and materials, and miscellaneous expenses incidental to such work are charged to the regular operating expenses and do not appear separately in the reports. There are, however, in addition, a number of mines which are mere explorations or developments, not having produced any ore, or old mines which, having been abandoned, have been reopened. It is difficult to obtain accurate information in regard to the expenditures for work done preparatory to the actual shipping of the ore, especially where a company has not been organized, but such data

[1] 1902 figures are exclusive of development work.

as could be secured are summarized in the following table:

TABLE 2.—*Development work, by states: 1902.*

	United States.	Michigan.	Minnesota.	Utah.	All other states.[1]
Number of mines	37	6	19	4	8
Number of operators	33	6	15	4	8

Wages	$31,219	$18,969	$3,405	$3,330	$5,515
Contract work:					
Amount paid	$216,168	.....	$215,868	$300	.....
Number of employees	286	.....	284	2	.....
Miscellaneous expenses	$68,533	$63,405	$2,346	$140	$2,642
Cost of supplies and materials	$143,541	$71,691	$66,310	$2,030	$3,510

[1] Includes operators distributed as follows: Alabama, 1; California, 1; Colorado, 1; Iowa, 1; New Jersey, 1; New York, 1; Pennsylvania, 2.

Table 2 shows that there were 37 nonproductive mines engaged in development work in the United States in 1902, employing 28 salaried officials and an average of 267 wage-earners, who received $177,317; the cost of supplies and materials being $143,541 and the miscellaneous expenses $68,533. These mines were capitalized at $2,685,000.

While these figures do not represent the full amount of expenditures for this class of work during 1902, they give some idea of the expense necessary before mines become productive. The most active exploitation of new deposits was in the states of Minnesota and Michigan. In most of the older states, such as New Jersey and New York, little exploratory work was done, except by active companies; such work was included in the reports of the active mining operations of these companies.

In addition to the mines included in the above table, there were 220 mines which appear to have been entirely inactive during 1902 as regards production or development work, no expenses for such work having been reported.

The mines classed as idle should not be considered as including abandoned mines or openings which have been idle for a long time with no effort made to revive them, nor do they include mines which have been dismantled. The purpose was to add to the record statistics covering such mines or operations as may be producers in the near future.

Capital stock of incorporated companies.—It is difficult to arrive at a fair determination of the proportion of capital stock and bonds properly chargeable against iron ore mines when operated by corporations owning blast furnaces and rolling mills, coal mines, railroads, etc., or by companies subordinate to parent organizations, or where the mining property is leased. Thus, A leases an iron ore property to B, who for this lease pays either a definite sum or, more often, a fixed or sliding scale royalty per ton for the ore taken out for a given time, usually a minimum annual output being stipulated. The operations may be upon a small part of the property owned by A, but if A places a value upon it, this value would probably include the entire tract. B can fix no value for the iron ore property, being merely a lessee, and would probably base his valuation upon the royalty he pays capitalized, which will be constantly changing as the mines are worked energetically or otherwise, or as the demand for ore is active or slack. The owner or the lessee may or may not be interested in the manufacture of iron. There are cases where the mines of an iron producing company are worked under lease for the advantage of another company, because of the location of the deposit as related to the works of the owner or the lessee.

In some instances companies organized years ago with moderate capital own or control large mines or land containing reserves of ore, the properties representing many times the capital stock of the company. In one instance there is a record of a company whose dividends in one year equalled the entire capitalization of the company. On the other hand, organizations capitalized in late years have iron ore holdings of comparatively small value, or are apparently over capitalized if the market value of the stock is considered. In the state of Minnesota some mines are owned in fee simple; others are on lands belonging to the state, which issues a mining lease at a fixed royalty. Some of these mining leases were secured by parties who sold them for a lump sum varying according to the amount of ore which is believed to exist on the property, or leased the property subject to the first and also a second royalty, usually from 5 to 20 cents per ton, a minimum amount of ore being specified to be won each year. In such cases the companies operating the mines are in reality sublessees, and there are instances where a third lease has been made, and the par value of the stock may not represent anything like the true value of the ore deposit. In some of the Southern states a number of mines are worked by mining companies, who win the ore from the deposits and deliver it f. o. b. at the mine at a fixed rate, which is paid by the owners of the property, and in this case the returns from this mining company would merely represent the value of the equipment used, and would not include the value of the ore property, which may be many times greater than that of the machinery, tools, and appliances used by companies which are really contractors.

In the Southern states and in the Lake Superior region many mines are leased, the capitalization of the operating company representing merely the value of the lease and not of the land. In addition to earnings on the capital stock of the company a fixed or, in some cases, a sliding royalty is paid, which, in the latter case, is based upon the market price of the ore; this royalty value is not recognized in the capitalization.

The following table presents the details of the capitalization of the incorporated companies:

TABLE 3.—CAPITALIZATION OF INCORPORATED COMPANIES: 1902.

[1] Includes companies distributed as follows: Connecticut, 1; Kentucky, 3; Massachusetts, 1; Montana, 2; North Carolina, 3; Texas, 1; Utah, 2; Wyoming, 1.
[2] Includes companies distributed as follows: Connecticut, 1; Kentucky, 3; Massachusetts, 1; Montana, 1; North Carolina, 1; Texas, 1; Utah, 2.

In the statistics presented in Table 3, where the iron ore lands were owned by companies operating blast furnaces, steel mills, or other industrial enterprises, an effort was made to secure an approximate proportion of the capitalization which would properly be chargeable against the iron ore mines, but without success, and in such cases the statistics are for the entire capitalization of the company.

The table shows that a large proportion, 64.7 per cent, of the capitalization of stock and bonds was reported from the iron mines in Michigan, Minnesota, and Wisconsin, which, with the exception of a few outlying mines, are embraced in the Lake Superior region. These three states produced 76.1 per cent of all the ore mined in 1902.

Next to the Lake Superior region, Colorado shows the largest capitalization, but much of the iron won in that state is from mines of the precious metal. In some instances this argentiferous iron ore is the only mineral at present won from the operation, and there-

PLATE I.—PIONEER AND CHANDLER MINES AT ELY, MINNESOTA.

fore the entire capitalization (originally based on the supposed value of the mine as a precious metal producer) is included in the iron ore report.

Alabama ranks next to the Lake Superior region and Colorado in the capitalization, as would naturally be expected from the large amount of iron ore produced. New York, New Jersey, Virginia, Pennsylvania, and Georgia follow in the order named, the remaining states being comparatively unimportant, so far as the capitalization of their iron mining companies is concerned.

In the year 1902 the capitalization, including funded debt, of 183 incorporated companies owning active iron ore mines reached a total of $247,798,970. In the year 1889 returns were secured from the 592 different mines of the value of the land, buildings and fixtures, tools and implements, and the amount of cash and stock on hand, showing a total of $109,766,199. Therefore, no information of comparative value is obtainable from a study of the reports of the capital invested in iron ore mines at the two census periods.

Employees and wages.—The following table shows the average number of wage-earners employed during each month in iron ore mining, by states and territories:

TABLE 4.—AVERAGE NUMBER OF WAGE-EARNERS EMPLOYED DURING EACH MONTH, BY STATES AND TERRITORIES: 1902.

[1] Includes operators distributed as follows: Connecticut, 1; Kentucky, 3; Massachusetts, 1; Montana, 3; New Mexico, 1; North Carolina, 3; Texas, 1; Utah, 4; Vermont, 1; West Virginia, 1.

These statistics show practically steady employment in such states as Alabama, Georgia, Tennessee, and Virginia, where the climatic conditions do not interfere with mining operations; and even in the states of Minnesota, Michigan, and Wisconsin, the variation in the number employed was less than generally presumed to be the case. This was undoubtedly due to the fact that the demand for ore encouraged a considerable amount of "dead work" and underground exploitation during the winter months. It is probable that figures for the year 1903 would show considerably greater variation between the seasons than those for 1902.

While the states of Minnesota and Michigan produced 76.7 per cent of the iron ore mined in the United States in 1902, the average number of wage-earners in those states represented only 58.5 per cent of the total for the country, and a calculation shows that for each wage-earner in those states 1,156 tons of iron ore were produced. Similar estimates for important producing states and for the country appear in the following table, to which the figures for 1889 have been added for the purpose of comparison:

TABLE 5.—*Tons of iron ore produced per wage-earner, by states: 1902 and 1889.*

[1] Includes Virginia only.
[2] Includes Georgia only.
[3] Includes Connecticut, Kentucky, Maryland, Massachusetts, Montana, New Mexico, North Carolina, Texas, Utah, Vermont, West Virginia, and Wyoming.
[4] Includes Connecticut, Delaware, Idaho, Kentucky, Maine, Maryland, Massachusetts, Montana, New Mexico, Oregon, Texas, Utah, and Washington.

It should be pointed out, in connection with the foregoing table, that the increase in 1902 over 1889 in the productive capacity per wage-earner is probably considerably less than is indicated by the figures, owing to the difference in the method of computing the average number of wage-earners at the two censuses.

An analysis of the statistics of wage-earners presents some interesting features. In Table 14, showing the detailed statistics, it will be noted that out of a total of 38,851 wage-earners, 23,082 are reported as employed below ground. That is, of the total number of wage-earners engaged in the iron ore industry 59.4 per cent are employed below the surface, the remainder being engaged upon surface mining or upon the work above ground. It is also shown that out of a total of 38,851, those returned as miners and miners' helpers, number 20,849, which suggests that slightly over one-half of those engaged in the iron ore industry may be considered as actually digging the ore.

As already stated, exact comparisons between the number of wage-earners at the Eleventh and Twelfth censuses can not be made, by reason of the fact that in 1902 the number of employees was reduced to the basis of practically continuous work (300 days) during the year. However, out of a total of 37,707 employees reported in 1889, 19,708 were returned as working below ground. The miners and laborers below ground, who may be considered as representing miners and miners' helpers, showed a total of 18,911 in 1889. The miners engaged in large open-cut operations were classed as laborers, and if the number of these be added to the above total, and this again corrected for the employees who were not actually helpers, the resulting figure indicates that practically the same ratio held good in 1889 as in 1902, namely, that about one-half of the wage-earners at iron ore mines may be considered as having actually dug the ore.

Table 14 shows also that a number of the miners worked above ground, and that a large proportion of the unclassified labor was employed below the surface. The unclassified labor represented about 29.9 per cent of all those engaged in the iron ore industry. This is accounted for by the fact that in a number of the large open-cut mines, where the operations were carried on by steam shovel, the only skilled help was really those engaged in the handling of machinery, trains, etc.

Table 6 shows for 1902 the distribution of wage-earners according to daily rates of pay, by states.

TABLE 6.—DISTRIBUTION OF WAGE-EARNERS ACCORDING TO DAILY RATES OF PAY, BY STATES AND TERRITORIES: 1902.

[Each cumulative percentage shows the proportion of the total number receiving a wage as great as, or greater than, the lowest wage of the given wage group.]

[1] Includes 8,105 wage-earners, paid by the ton, for whom average daily earnings are shown.
[2] Less than one-tenth of 1 per cent.
[3] Includes Colorado, Connecticut, Georgia, Kentucky, Maryland, Massachusetts, Missouri, Montana, New Mexico, North Carolina, Ohio, Texas, Utah, Vermont, West Virginia, and Wyoming.

PLATE II.—AUBURN MINE, MILLING PIT, MESABI RANGE, MINNESOTA.

In the preceding table the distribution of wage-earners, according to daily rates of pay, is shown separately for the 8 states which reported more than 1,000 wage-earners, and also for New York, which is the only other state in which the number of wage-earners approximated 1,000. These 9 states gave employment to 36,687 wage-earners, or 94.4 per cent of the total number employed in this industry in the United States. Of the states for which statistics are presented separately, Minnesota shows the highest rates of pay, 97.1 per cent of the wage-earners having received at least $1.75 per day, and 34.5 per cent of these $2.25 per day or over. The rates of pay were only slightly lower in Michigan and Wisconsin. In the former state 11.2 per cent received between $1.50 and $1.74, while in Wisconsin the proportion with rates of $2.25 or over was considerably smaller than in Minnesota. Michigan, Minnesota, and Wisconsin constitute the Lake Superior district, and the rates in these 3 states were materially higher than those in the other states. In each of the 3 states of the Lake Superior district the bulk of the wage-earners received $2 per day or over, while in each of the other states for which statistics are shown separately, practically all the wage-earners received less than $2 per day.

The state in which the daily rates of pay approached most nearly those of the Lake Superior district is New Jersey, where the range of wages for 91.4 per cent of the employees was from $1.25 to $1.99. New York, Alabama, Pennsylvania, and Wisconsin follow in the order named. New York shows a considerable number with rates of less than $1.25 per day and a comparatively small number who received as much as $1.75. In Alabama the bulk of the wage-earners, 89.3 per cent, received between $1 and $1.99. There was very little difference on the whole between the rates paid in Pennsylvania and those paid in Tennessee. The proportion receiving $1.75 or over was greater in Tennessee, but the number who received less than $1 was so large as to offset this. Rates were lower on the whole in Virginia than in any other state which reported a large number of wage-earners, only 7.1 per cent of the total number having been paid as much as $1.50 to $1.74 per day.

Table 7 shows the distribution of the wage-earners employed in 1902 in the mining of iron ore among the several occupations and according to daily rates of pay. For each occupation the average number employed during the year at specified rates, and the percentages which these numbers form of the total number, are given. In an additional column these percentages are accumulated, thus rendering it possible to determine what proportion of the total number received as much as, or more than, a given rate.

TABLE 7.—DISTRIBUTION OF WAGE-EARNERS ACCORDING TO DAILY RATES OF PAY: 1902.

[1] Includes 8,105 wage-earners paid by the ton, for whom average daily earnings are shown.

[2] Less than one-tenth of 1 per cent.

More than half, 52.8 per cent, of the total number of engineers received $2 or over. Most of the engineers are, however, concentrated in the $2 group, and the two groups below, 71.3 per cent, receiving between $1.50 and $2.24. The wages for firemen are seen to be somewhat lower than those for engineers. For firemen the lower-limit median rate group is $1.75, while for engineers it is $2; in each case a greater number of employees is included in the median group than in any other.

The range of wages for over 82 per cent of machinists was from $1.50 to $2.74. The median rate lies between $2 and $2.24, and the distribution both above and below that rate is comparatively regular. In this occupation, also, the median group comprises a greater number of men than is found at any other rate.

The table shows a very wide range in the rates paid to miners. The wages for the bulk of the employees ranged from $1 to $2.74, with the median at $2. By far the greater portion of miners' helpers are concentrated in three wage groups, the range for 76.9 per cent being from $1.50 to $2.24.

The median wage for timbermen and track layers was between $2 and $2.24, and the bulk of the employees received from $1.50 to $2.74.

Almost half of the boys employed, 48.3 per cent, received between 50 cents and 75 cents; 27.2 per cent received less than 50 cents, and 19.1 per cent received between 75 cents and $1. The median rate for all other wage-earners was between $1.75 and $1.99. The wages for 92.3 per cent of the total number ranged from 75 cents to $2.24.

In the year 1889, also, data in regard to the wages paid the different classes of labor, both above and below ground, were obtained. The returns were in the form of average daily wages and may be summarized as follows:

OCCUPATION.	Average wages per day above ground.	OCCUPATION.	Average wages per day below ground.
Foremen and overseers	$2.40	Foremen and overseers	$2.46
Mechanics	1.90	Miners	1.91
Laborers	1.29	Laborers	1.60
Boys under 16 years	0.62	Boys under 16 years	0.82

Mechanical power.—The detailed summary shows that 119,558 horsepower was used at iron ore mines in the various operations requiring power. This power was applied chiefly through 1,132 steam engines, with a horsepower of 102,878, or 86 per cent of the total. There were also 11 gas or gasoline engines with a horsepower of 86, 11 water wheels having a horsepower of 1,010, and 260 miscellaneous appliances with a horsepower of 15,444. In addition to this primary power 35 electric motors were used, their total horsepower being 937; 140 horsepower was rented to other establishments.

At the census of 1889, 1,109 steam boilers, with a total horsepower capacity of 57,976, were reported by iron ore mines. It was stated in the report on iron ore at that census that these boilers furnished steam to 1,093 steam engines, including air compressors, hoisting machinery, and engines for driving washeries, etc. In 1902 the mechanical power was applied for the purposes for which power is commonly employed in mining work, namely, for hoisting the ore from the shaft, for subsequent beneficiating treatment, for operating steam shovels and dredges in open-cut mining, pumping and ventilating machinery, mechanical haulage, air compressors, electric lighting, drills, etc.

Table 14 shows also the distribution of the power among the several states; Michigan led in the horsepower employed, having 47,395 horsepower, or 39.6 per cent of the total; Minnesota had 25,332 horsepower, or 21.2 per cent of the total; Alabama, 10,370 horsepower, or 8.7 per cent; New Jersey, 6,684 horsepower, or 5.6 per cent; and New York, 6,015, or 5 per cent. In the other states the amount of mechanical power used was smaller, but on the whole proportionate to the extent of their operations.

Production.—At the Eighth and Ninth censuses the statistics of production were not collected in the same manner as in subsequent census years. In 1860 the number of tons of iron ore mined by the owners of blast furnaces was reported separately from the production of what were considered strictly mining companies. The report shows that the blast furnace establishments used 2,309,975 short tons in 1860, and that in addition 908,300 short tons were produced by mining companies, a total of 3,218,275 short tons, equivalent to 2,873,460 long tons.

In 1870 the total amount of iron ore produced by the mines reporting was 3,395,718 short tons, equivalent to 3,031,891 long tons; in addition some ore was produced by the owners of blast furnaces which the Bureau of the Census estimated at from 800,000 to 900,000 long tons, so that, taking the first named figure, at least 3,831,891 long tons of iron ore were mined in 1870. At the Tenth, Eleventh, and Twelfth censuses the data were obtained from all mines irrespective of their ownership or their relation to blast furnaces. The following statement gives a comparison of the figures for these censuses:

Production of iron ore: 1860 to 1902.

CENSUS YEAR.	Quantity (long tons).
1860	2,873,460
1870	3,831,891
1880	7,120,362
1889	14,518,041
1902	35,567,410

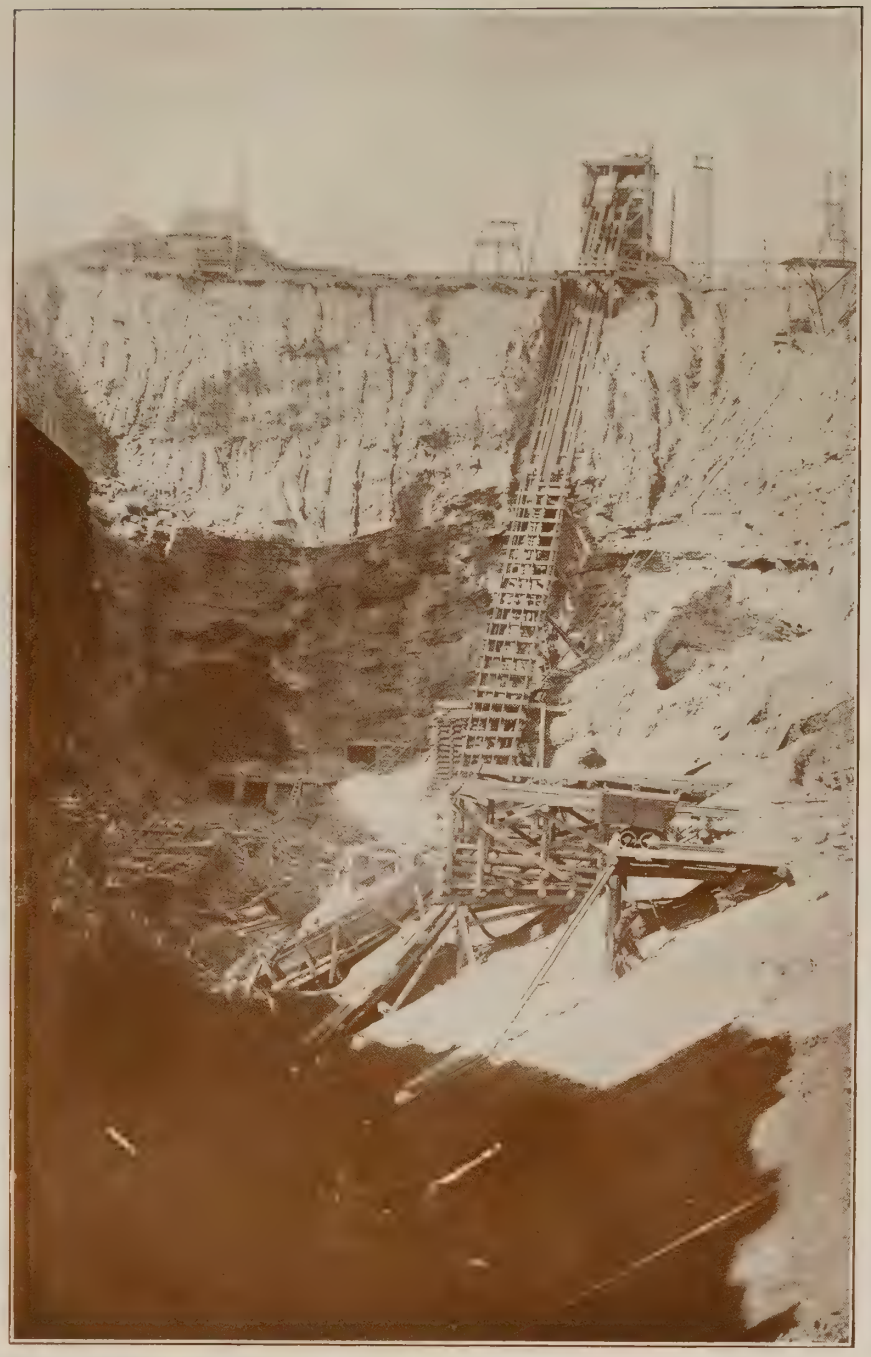

PLATE III.—NO. 2 PIT, ADAMS MINE, EVELETH, MINNESOTA.

PLATE IV.—STEEL SHAFT HOUSE, ADAMS MINE, FIRST ON THE MESABI RANGE.

There is, as mentioned, some uncertainty in regard to the production of iron ore at the Eighth and Ninth censuses, but in comparing the statistics of the various censuses it will be noted that the production in 1880 was nearly double that of 1870, while in 1889 the output was twice that of 1880. In 1900, according to the figures of the United States Geological Survey (the census of 1902 was taken at a time thirteen years removed from 1889), the proportion over 1889 was almost identical. Thus, in every decade since 1870 the production of iron ore in the United States has practically been doubled.

The following table presents for each class of iron ore the amount produced in the census years 1902, 1889, and 1880, together with the percentages which these amounts formed of the total for all classes:

TABLE 8.—*Production of iron ores by varieties, with per cent of total: 1902, 1889, and 1880.*

VARIETY.	1902		1889		1880	
	Quantity (long tons).	Per cent of total.	Quantity (long tons).	Per cent of total.	Quantity (long tons).	Per cent of total.
Total	35,567,410	100.0	14,518,041	100.0	7,120,362	100.0
Red hematite	30,532,149	85.9	9,056,288	62.4	2,243,993	31.5
Brown hematite	[1]3,318,759	9.3	2,523,087	17.4	1,918,622	26.9
Magnetite	1,688,860	4.7	2,506,415	17.2	2,134,276	30.0
Carbonate	27,642	0.1	432,251	3.0	823,471	11.6

[1] Includes 13,275 tons of manganiferous ore.

There has been an increasing preference for rich and easily smelted iron ores, and considering the different varieties of ore, it will be found that the amount of red hematite reported in 1880 was but 31.5 per cent; in 1889, 62.4 per cent; and in 1902, 85.9 per cent of the total output. The brown hematite, although augmenting in the amounts mined, indicates a decided decrease in percentages of the total; from 1,918,622 long tons in 1880 this class of ore increased to 2,523,087 long tons in 1889 and 3,305,484 long tons in 1902, the percentages at the three censuses being respectively 26.9, 17.4, and 9.3 per cent. On the other hand, the magnetites and carbonates have shown a decline, not only in total production, but also in percentage. The former contributed 30 per cent (2,134,276 tons) of the total in 1880, 17.2 per cent (2,506,415) in 1889, and 4.7 per cent (1,688,860) in 1902. The carbonate ore has fallen from 823,471 long tons, 11.6 per cent, in 1880 to but 27,642 tons, one-tenth of 1 per cent, of the total in 1902.

The production of iron ore of the different varieties, by states, in the year 1902 was as follows:

TABLE 9.—*Production of iron ore, by states and territories and varieties: 1902.*

[Long tons.]

STATE OR TERRITORY.	Total.	Red hematite.	Brown hematite.	Magnetite.	Carbonate.
United States	35,567,410	30,532,149	[1]3,318,759	1,688,860	27,642

[1] Includes 13,275 tons of manganiferous iron ore used in the manufacture of spiegeleisen.

Considering the individual states it is evident that those located in the Lake Superior region and in the Southern and Western states have shown an almost constant increase. In the Middle Atlantic and New England states, however, the bog, brown hematite, fossil, and magnetite ores, which formerly were the chief reliance of the local blast furnaces, have been replaced by the richer Lake Superior ores, and therefore show a marked falling off. The states will be considered in the order of their prominence in 1902.

Minnesota.—This state in 1902 contributed 15,137,650 long tons of iron ore, a greater amount than was produced by the entire country in 1889. This shows the unprecedented increase in thirteen years of eighteen times the amount contributed in 1889, viz, 864,508 long tons, when Minnesota occupied fifth position, while in the previous census year, 1880, no iron ore was mined in the state, the first production being in the year 1884. Since the year last mentioned the state has shown a phenomenal and practically an uninterrupted advance in the yearly output. The ore is obtained from the Vermilion and Mesabi ranges, that secured from the former being a hard specular or red hematite ore, while in the latter the red and brown hematites are much softer and in many localities quite finely comminuted. No true limonite ore is shipped from Minnesota, but the degree of hydration of some of the red hematites and the prevailing color encouraged the trade recognition of part of the state's product as brown hematite.

A comparison of the production and value of Minnesota iron ores at the last two census years is as follows:

Production and value of Minnesota iron ore: 1889 and 1902.

YEAR.	Quantity (long tons).	Value.
1889	864,508	$2,478,041
1902	15,137,650	23,989,227

Michigan.—In the year 1880 the amount of iron ore mined in Michigan was 1,640,814 long tons, giving the state second rank, Pennsylvania being first. The output increased in 1889 to 5,856,169 long tons, Michigan ranking first and continuing to hold that position until 1901. In 1902 the production was 11,135,215 long tons, nearly double that at the previous census. The greater portion of this ore was of high grade, although in late years some siliceous ores comparatively low in iron content and also low in phosphorus have been won for use as a mixture in the furnaces with richer ores low in silica. The three ranges from which this ore was mined, the Marquette, Menominee, and Gogebic ranges, are all located closer to shipping ports and to the principal pig iron manufacturing centers than the Minnesota ranges, and the ores therefore command a higher relative value at the mine than those of Minnesota, as will be seen from the following statement:

Production and value of Michigan iron ore: 1880 to 1902.

YEAR.	Quantity (long tons).	Value.
1880	1,640,814	$6,034,648
1889	5,856,169	15,800,521
1902	11,135,215	26,695,860

Alabama.—In 1880 Alabama was a comparatively unimportant iron ore producer, the quantity obtained being 171,139 long tons, giving the state seventh position. The extensive deposits of fossil ores, particularly in the Birmingham district, located close to supplies of fuel and flux, were, however, the foundation of an important pig iron industry, and the amount of ore mined increased in 1889 to 1,570,319 long tons, which was more than doubled in the year 1902, when 3,574,474 long tons were won, as shown in the statement below. These ores, however, are not of so high a grade, nor are their values so great, as those of the Lake Superior district. In addition to the red hematite ores referred to, important deposits of brown hematite have been developed, and this class of mineral represents about one-third of the iron ore supply of the state. Some exploitation has also been carried on for the purpose of utilizing magnetites which occur in apparently moderate quantities.

Production and value of Alabama iron ore: 1880 to 1902.

YEAR.	Quantity (long tons).	Value.
1880	171,139	$201,865
1889	1,570,319	1,511,611
1902	3,574,474	3,936,812

Virginia and West Virginia.—The iron industry in Virginia was established early in the seventeenth century, but as charcoal was the fuel used in the old furnaces, the amount of ore consumed, which was usually mined within convenient reach of the furnaces, was small. The production for 1880 in Virginia and West Virginia was 217,448 long tons. The output in 1889 was 511,255 long tons, and in 1902, 987,958 long tons. The iron ore supply of the Virginias has been supplemented in late years by the importation of iron ores from the Lake Superior region. Most of the iron ores now obtained in the Virginias are of the brown hematite variety, but some red hematites and magnetites are also mined. The production and value for the last three census years are given as follows:

Production and value of Virginia and West Virginia iron ore: 1880 to 1902.

YEAR.	Quantity (long tons).	Value.
1880	217,448	$530,943
1889	511,255	935,290
1902	987,958	1,667,456

Tennessee.—Tennessee occupied tenth position as a producer of iron ore in 1880, eighth in 1889, and fifth in 1902, its output consisting of brown and red hematites, the amounts and values being as follows:

Production and value of Tennessee iron ore: 1880 to 1902.

YEAR.	Quantity (long tons).	Value.
1880	93,272	$147,181
1889	473,294	606,476
1902	874,542	1,123,527

Pennsylvania.—Pennsylvania, which produced practically half of the total pig iron manufactured in the United States in 1902, might be supposed to be the largest iron ore producing state, and prior to improved transportation facilities this was the case. In the year 1880 it occupied first position, with a total of 1,951,496 long tons, declining to third in 1889, the output being 1,560,234 long tons, and to sixth place in 1902, produc-

PLATE V.—MOUNT IRON MINE, MESABI RANGE, LOOKING EAST ACROSS PIT, SHOWING TWO STRIPPING AND THREE ORE LEVELS.

ing only 822,932 long tons, due to the use by Pennsylvania furnaces of rich ores from other sections of the country. Magnetites predominated, brown hematite being second and red hematite least in importance. A statement of the quantity and value at each of the last three census years follows:

Production and value of Pennsylvania iron ore: 1880 to 1902.

YEAR.	Quantity (long tons).	Value.
1880	1,951,496	$5,517,079
1889	1,560,234	3,063,534
1902	822,932	1,225,453

Wisconsin.—The bulk of the iron ore obtained in Wisconsin is secured from the Gogebic and Menominee ranges, which extend from the state of Michigan into Wisconsin. Most of the ore is red hematite, a small proportion being brown hematite. This state contributed 37,000 long tons of iron ore in 1880, 837,399 long tons in 1889, and 783,996 long tons in 1902, the quantities and values being as follows:

Production and value of Wisconsin iron ore: 1880 to 1902.

YEAR.	Quantity (long tons).	Value.
1880	37,000	$73,000
1889	837,399	1,840,908
1902	783,996	1,800,864

New York.—In earlier years large amounts of iron ore of all four classes were obtained from various deposits in New York, the total for 1880 being 1,126,899 long tons, giving the state third position. The output had risen in the year 1889 to 1,247,537 long tons, but in 1902 there was a decline to 555,321 long tons. The bulk of New York ores mined are magnetites, but some red and brown hematites are found. A statement for the last three census years follows:

Production and value of New York iron ore: 1880 to 1902.

YEAR.	Quantity (long tons).	Value.
1880	1,126,899	$3,654,872
1889	1,247,537	3,100,216
1902	555,321	1,362,987

Other states and territories.—None of the other states or territories contributed over one-half million tons in 1902, and they will not, therefore, be considered individually. In the following table the production of these remaining states and territories in 1902, 1889, and 1880, is given, together with the total value of the iron ore mined:

TABLE 10.—*Quantity and value of iron ore, by states and territories: 1880 to 1902.*

STATE OR TERRITORY.	1902		1889		1880	
	Quantity (long tons).	Value.	Quantity (long tons).	Value.	Quantity (long tons).	Value.

Oregon and Washington	.....	.....	26,283	39,234	[6] 6,225	4,669
Texas	6,516	6,434	13,000	19,750	3,214	8,100

[1] Includes 13,275 tons of manganiferous iron ore, valued at $52,371.
[2] Includes Vermont; no production from Maine.
[3] Maryland only.
[4] Montana only.
[5] Also Wyoming.
[6] Oregon only.

The predominating ores obtained from these states are brown hematite from New England, Delaware, Maryland, Georgia, Colorado, Oregon, Washington, and Texas; magnetites from New Jersey, North Carolina, and New Mexico; red hematites from Missouri and Wyoming; and carbonates from Ohio.

Table 11 shows in a general way the status of the iron ore industry in the United States by important districts.

TABLE 11.—*Summary, by districts: 1902.*

Horsepower	79,094	15,916	17,233	4,786	1,095

[1] Includes Michigan, Minnesota, and part of Wisconsin.
[2] Includes Alabama, Georgia, and Tennessee.
[3] Includes Colorado, Montana, New Mexico, Utah, and Wyoming.

No attempt was made to include in Table 11 the statistics for the entire country, as such data are presented in other tables, but the states of Michigan, Minnesota, and Wisconsin are grouped in the Lake Superior region,

while the southern district includes the iron ore mines of Alabama, Georgia, and Tennessee. Other important groups of states, such as New York and New Jersey combined with Pennsylvania, and Virginia combined with West Virginia, are also shown, and the Rocky Mountain region is presented as a whole to indicate the extent of iron ore production in that section of the country. The comparisons suggested by the table will be understood as covering the districts generally, and not as applicable to the individual mines.

It will be noted that 151 mines in the Lake Superior region produced 26,977,404 long tons, equivalent to 178,658 long tons per mine, while in the Southern district 100 mines produced 4,779,570 long tons, an average of 47,796 long tons per mine, mainly attributable to the difference in the character of the deposits of the two regions. The Lake Superior ores occur in large beds or lenses, making the local development extensive, and encouraging the introduction of labor-saving appliances. The high grade of ore mined, as compared with that in other parts of the country, is also responsible in part for the extensive development. In the Southern district the ore deposits are either in stratified beds or in pockets, and the local developments while important are not so large, nor is the ore as rich as in the Lake Superior region; therefore, the application of labor-saving appliances is not justified to the extent it is in the Lake Superior district.

Imports.—While enormous quantities of rich iron ores are produced in the United States, large amounts of iron ores are imported, principally from Cuba (where all of the mines are operated by American capital), and used in blast furnaces located in the eastern portion of the United States. Small quantities are also brought in to supply the charcoal furnace located at Port Townsend, Wash., and for other uses than smelting.

The following table shows the quantity and value of the iron ore imported during the years 1889 to 1902:

TABLE 12.—*Quantity and value of iron ore imported: 1889 to 1902.*

YEAR.	Quantity (long tons).	Value.	YEAR.	Quantity (long tons).	Value.
1889	853,573	$1,852,392	1896	682,806	$1,036,917
1890	1,246,830	2,854,118	1897	489,970	678,912
1891	912,864	2,456,521	1898	187,208	255,548
